Cultural Significance of Broadcasting*

THE speed with which in a decade or so broadcasting has passed from being the interest or hobby of an expert few into the pleasure and recreation of millions has tended to concentrate attention on the purely scientific and technical developments which have made this change possible The reactions of this rapid growth upon the listener himself, the new problems which broadcasting itself may offer, have escaped attention except by a few, and it is only slowly and with difficulty that broadcasting is emerging from the toy stage to that of laboratory and workshop for human culture.

The scientific inquiries into international aspects of broadcasting, which have been initiated by the International Committee of Intellectual Co-operation of the League of Nations, afford an example of the widening field of scientific research and the possibilities, and responsibilities, of what may be termed social research which arise out of technical advance, and are in keeping with those studies of the effect of the cinematograph on education, instruction or national life visualised by the first International Congress on Educational Cinematography in Rome last April. The first of the inquiries set on foot by the International Committee was a survey of educational broadcasting throughout the world The substantial volume which embodies its results contains an authoritative account of experiments, results and projects in twenty-five countries, as a result of which a

* School Broadcasting (Intellectual Co-operation Series.) Pp 208 7s 6d Broadcasting and Peace (Intellectual Co-operation Series) Pp 232. 7s 6d (London George Allen and Unwin, Ltd, 1934)

statement of the leading principles of school broadcasting has been prepared which should be an invaluable guide in further experiment leading to the perfecting of this new method

The inquiry makes it clear that school broadcasting has a place of its own in primary, secondary and higher education, but the technique of its use, the choice of subjects, methods of presentation, manner of incorporation in the general framework of class-room courses, and the full potentialities of the method, are only being evolved Studies of this type are of great assistance in the development of an adequate technique They throw light on the true reasons for failure, and are correctives to its indiscriminate use or rash condemnation

The second investigation was a study of broadcasting in relation to peace, to which indeed a brief section in the first report is devoted The dangers which broadcasting may present in regard to international peace and goodwill have been made plain abundantly by unfortunate incidents between Germany and Austria in the last two years The dangers of the use of this method as a means of political propaganda are less obvious but none the less real, and the report which the International Committee has produced on this question will repay study by all who approach broadcasting in the spirit of scientific inquiry

The third inquiry upon which the International Committee is now embarking relates to the possibilities, problems and methods of cultural broadcasting in its widest sense, and may prove to be the most fundamental and interesting of the three researches The investigation deals with the organisation and contents of programmes and their national and international co-ordination, the possibility of broadcasting university extension courses, the social training of listeners, the announcement of scientific discoveries, instruction in literature and history and the teaching of foreign languages

Studies of this order at once throw into relief the difference between the broadcast to an unseen audience and the lecturer who can see and adjust his lecture to the reaction of the audience in front of him Beyond this there is the development of the precise technique which makes it possible to convey new vistas to a voluntary adult audience, without any suggestion of superiority or of the schoolroom Pooling of experience and ideas on this difficult art is a first step to a scientific technique

It is at least arguable whether the technique of broadcasting will not be ultimately more art than science Unquestionably, however, psychology has an important contribution to make in this field, and at the International Congress of Anthropological and Ethnological Sciences in London last August, Prof T H Pear pointed out several lines of research which still await the attention of psychologists and anthropologists Prof Pear's paper in itself indicates that the psychologist is alive to the problems which broadcasting and the film present As an observer of human experience and behaviour, he cannot ignore the serious disturbance which they both represent in the life of the citizen, and he must attempt to find the reasons for the likes and dislikes which he observes

Problems of this type present in fact a striking field for laboratory work, but as Prof Pear emphasised, with certain special exceptions in regard to school broadcasting and the request for opinions on the broadcasting of drama, practically no systematic research has been carried out in Great Britain into the pyschological and other problems created by broadcasting Little intensive or extensive research even into listeners' likes and dislikes and the reasons for them has been made, and the evidence that those responsible for the provision of radio programmes are really anxious to discover the views of the general public on the material is unconvincing

Prof Pear suggests that this omission is due to the fear that the results of such inquiries would necessitate either a grading up or a grading down of the programmes If this is the correct explanation, such an attitude to research is unworthy of an industry based so fundamentally on scientific research as the broadcasting industry Indeed, this attitude inevitably foreshadows the decay of the institutions or organisations which hold it Change and development cannot be avoided by mere passivity, and if the broadcasting authorities are not prepared to conduct research into these fundamental problems of their art, sooner or later their power and influence will pass into the hands of those prepared to undertake the work and apply its results Nor can society tolerate for long any organisation which does not seek to equip itself continuously to render ever more effective service based on the full, impartial and fearless exploration of the whole domain which it affects to control.

The reports and the papers to which we have referred indicate, moreover, that scientific workers themselves have special interests and responsibilities in this matter. On one hand, the possibilities

which broadcasting presents as a means of diffusing scientific knowledge, and also of carrying on that educational work which is so essential if the ordinary citizen is to acquire an adequate general background for the kind of life he is called upon to live in these days, have been neither fully utilised nor explored. Evidence presented in the report on educational broadcasting already indicates a considerable volume of opinion in Belgium, France, Switzerland, Germany and the United States as to the value of broadcasting in relating scientific work to the general interests and activities of the community Scientific workers have yet to seize the opportunities for exposition which here confront them when they have qualified themselves by acquiring the requisite technique.

On the other hand, to the true spirit of science, the fields of investigation touched upon by Prof Pear represent an even greater attraction There could scarcely be found a more inspiring example of the twin responsibility and challenge in respect of social research which the application of scientific discoveries throws down to the man of science himself, than these fields of investigation which now lie before us, in broadcasting and cinematography alike, demanding his close co-operation if they are to be possessed for the welfare of civilisation and not contribute to its undoing

Reviews

Isaac Newton

Isaac Newton · a Biography By Louis Trenchard More. Pp xiii+675 (New York and London. Charles Scribner's Sons, 1934) 18s net

AT last we have an adequate biography of Newton Prof More would not wish us to say it was perfect—that would have been impossible—but he has spent seven years reading the documents and considering them, and he does not hesitate to tell his opinion, even if unfavourable We have got into a period of biography where an unfavourable opinion has rather a preference for expression But Prof More is not that kind of biographer. He has a respect, almost a love for Newton, though far "this side idolatry", and deliberates a long time before he comes to an unfavourable opinion

Newton has fallen into bad hands among his editors and biographers Horsley was a person who did not see the difference of interest that future times would attach to works by Newton and lucubrations by Bishop Horsley Prof. More convicts him of quite definite suppression of documents which he examined, and which would have proved Newton a 'Socinian', or as we now say, a Unitarian Leaving Horsley aside, as too bad to mention, Brewster figures to Prof More in much the same way He, too, suppresses documents that he does not like One must make allowances for him. He presented Newton as *possibly* a *very mild* Socinian, and even then, was rebuked by a bishop for it But he must have got on Prof More's nerves. In fact, he wipes the floor with Brewster, after the presentation of each incident. He was indeed a most unsuitable person A biographer of someone whose greatest period of creation was at the Restoration, and who died more than two hundred years ago, ought to be imaginative, catholic, sympathetic with all and sundry, and Brewster was not that. The other biographers portray one point of view only Edleston seems to be careful and accurate, but has done only a scrap Rigaud's essay is the same The separate contributions to Greenstreet's volume are of very unequal merit, some are valuable, many are by good names, but some are quite off the mark Then there is Lieut-Col de Villamil, who astonished everybody by making no less than four capital discoveries, the chief of them appear to me the actual inventory of all the items which Newton's house contained, drawn up with extreme thoroughness, the actual list of Newton's books, now among the MSS of the British Museum, and an actual statement of his money affairs at his death, including a criticism of any dealings he had in South Sea stock Yet despite the richness of the material, the book in which he published it remains a poor affair

Newton was little understood in his time We cannot wonder. Scientific men are usually little understood, very few people care for pure logic, or are prepared for the surprising consequences, if it is pushed to the uttermost. But besides, Newton was habitually a silent man He was not a ready speaker His notion appears to have been, to say something conclusive and leave it at that, whether it was understood or not This sort of thing does not go to the heart of the ordinary man or woman But women had no influence in Newton's life He began life poor and ended it rich; yet he used no corrupt practices and was generous in giving. Opposition had a very bad effect upon him—for did he not *know* it to be unreasonable? Yet most people would say that he had not more opposition than was good for him, to

teach him the sort of world he was in His life was not a pathetic life; he had none of those amiable weaknesses that make us forgive a great deal to Goldsmith and Richard Savage He moved among ordinary men that we can visualise, such as Pepys, Hooke and Oldenburg But all seem to have felt that he was greater than they, and different, and that he required nothing from them Later, this feeling seems to have congealed into a spell, which accompanied him as an unwholesome and impenetrable aura This spell has been the greatest obstacle to acquiring a true view of Newton.

The incidents of Newton's life are indispensable, but only because his theories grew up among them I do not think that the scientific views were much changed by the incidents, but undoubtedly their presentation was His ideas are what matter to us now, the views that have, almost miraculously, kept their shape

I have often wondered why Newton made no capital discoveries in chemistry, which he studied and practised so assiduously, and made absolutely revolutionary discoveries in mechanics and optics. I think I know now The discoveries in optics were made because he was an unusually good experimenter, and knew, after he had "meditated", no man better, the immediate and ultimate inferences that his experiments required The discoveries in mechanics, the laws of motion and the philosophical system on which they are based, are just "meditations", the object being to find something that would stand metaphysically. Metaphysics was the bane of science in those days, but since it cannot be excluded, Newton built a wall, guaranteed to stand any attack, within which his mathematics could operate undisturbed His mathematical theorems in the "Principia", as well as his other very notable contributions to the science, are just inferences—of course *in excelsis*—from stated data But why did he add nothing to chemistry? Chemistry was much studied in Newton's day. Boyle was his friend, and Boyle has given us Boyle's Law Locke, also a friend, was a chemist, even an alchemist. Van Helmont's works are in his library Newton read the unprofitable volumes of the alchemists, I think to ascertain whether he could learn anything from them. In one of his letters, he speaks of them as "great pretenders" I think the phrase is sarcastic, meaning that you get nothing in the end

What then was Newton seeking? I admit that incidentally he was seeking transmutation But he did not find it I cannot believe that he laboured so long in vain There is a great resource if we want to ascertain Newton's undemonstrated ideas, upon subjects on which he had "meditated"—the "Queries" which he attached to the optics Many of the ideas which he had derived from his study of alchemy he put in the long, final query, No 31. Prof More quotes much of this query Reading it through, one sees that Newton was looking for a common basis of all matter, and the mechanism of the transmission of energy and gravitation across space From this point of view, Boyle's Law becomes a mere incident, which might be expected to become almost self-evident But we now know that there is a very long and thorny road to go before we arrive at a common basis of matter. We are scarcely agreed upon it yet, but let that pass Even supposing, what does not seem likely, that Newton had avoided *all* the pitfalls, and would have had nothing to do with a "phlogistic" theory, which proved such a will-o'-the-wisp to chemistry, he would have seen in face of him, beyond gross matter, the immense jungle of the carbon compounds, the molecules, the elements, the atoms of those elements, the structure of these atoms, the positive and negative element of electricity, and finally the quantum The spectrum, even, was unknown to Newton We can scarcely imagine the structure of the atoms being unravelled, apart from the spectrum. Except some astronomical examples, all measuring instruments were exceedingly crude The balances are shown with rough strings to the pans, nor was the dependence of chemistry upon a balance realised. So if we read through Query 31, and say "quite possibly right", we must remember that this rightness is only possible if we think in electricity I understate the task, but actually it was impossible, there was no body of facts such as we have now—for example, the periodic system, the "shoulders of giants" were wanting, from which Newton could look out over the future

At the present time we are surrounded by uncertainties. We must remember that Newton was rooted in certainties—in three at least. These were, the actual words of Scripture, the "geometry of Euclid and Apollonius", and the inferences of logic He was also endowed with a peculiar aptitude of devising and performing experiments. He "meditated" upon their consequences, by which we must understand that he saw, as none other has been able to do, all that they implied. That is the reason why, when he had arrived at a conclusion, he made no allowance whatever for those that questioned it, and at first, when he was a young man and unknown, they were very numerous. Later, when it was enough to say "Newtono suadente", I agree with Prof. More that the deference he enjoyed reacted unfavourably upon his character. Prof. More describes the early paper in which he demonstrated his optical theories to the Royal Society as a "work of art".

This is well said. Newton was an artist, though not in paint or stone. He was, apparently, contemptuously indifferent to any work of imagination. But no one who has read the "Principia", or any of his letters, or even seen his beautiful handwriting and signature, can doubt that he was an artist. He was an artist, because he loved beauty; he thought it the direct expression of the Divine, as it is presented to us. He had moreover the artist's temperament, which showed itself, as it did in Rossetti, in rather overbearing conduct.

We have seen all these grounds of certainty fade away. Geometry went first, because it was in the hands of people who had a common ground, and were able to realise when a theorem was proved. As to the Scriptures, whatever view we attach to the Bible story, we now regard the Bible—for the most part, and subject to some delegation of authority in matters of such importance—as a book among other books, to be examined textually and in substance, confronting different statements to see whether they agree, by any method that the higher criticism may choose to apply, estimating the contents by whether we think the thing did occur or did not. Most people, nowadays, would smile if they were asked to believe in Bishop Ussher's date for the creation, or the ages of the patriarchs, and Jonah's whale.

Now logic seems to have joined the other two on the same road, and to melt away "like wracks in a dissolving dream", and prove just nothing at all. We are told that if we "prepare" an experiment, we prescribe the answer also, which is always *yes*, if the question is not nonsensical. Exit "Q E D", and enter "Sez You".

Now that we can see Newton "in the round", we can form an estimate of his value, apart from what everybody knows and has known for two hundred years—that he was an incomparable genius in both theory and experiment. Roubillac was a great artist, and has caught most admirably in marble the expression which we can attach to his "meditations"—"the index of a mind forever voyaging through strange seas of thought, alone". Certainty was the note. Experiment, and inference, and experiment again—that was the indispensable key to progress; and a very good key it has proved, supposing "progress" is what we want, for it has made scientific men, where they are not leaders of the modern world, at any rate necessary authorities on all the things that other people want to answer and cannot.

But in deifying Newton, as he has been, rather grotesquely, deified up to the present, we must think of Lieut.-Col. de Villamil's "Inventory", and his list of books. Most people will read them with astonishment; it is possible some may comment "Stuffy old house. Not a single valuable piece of furniture. Crimson, a bad note. Stuffy old books. Not a single book of verse among them except those that he may have read at school. Not a single live book, except Galileo's 'De Systemate Mundi'. No Copernicus. No Kepler." They will issue from it with relief. There is no doubt that Newton appears in these authentic, if unsentimental, documents as a limited person. Nowadays we rather distrust certainty. We doubt whether we are the people to handle certainties, if someone would point one out. Besides, their field is too narrow and we have found that we can learn all we want to know from most regions by a few well-chosen experiments, and by the general bearing of the replies. To speak of geniuses alone, Shakespeare represents much more the kind of man who might tell us something we wanted to know. You find profundities among his words, but mixed up with guffaws and sniggers and the interjections of people who just happened to be by and were certainly not profound and had no wish to be. "We are such stuff as dreams are made on, and our little life is rounded with a sleep." Would you put an automatic pistol into the hands of a dream person? He might dissipate the dream.

R. A. S.

Hamites and Semites

Semitic and Hamitic Origins, Social and Religious. By Prof. G. A. Barton. Pp. xvi+395. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1934.) 17*s.* net.

MORE than thirty years ago, Prof. Barton wrote a book on Semitic origins when he was very strongly under the influence of Robertson Smith. Owing to the strides which have been made in the study of the prehistory of Egypt and western Asia since that date, Prof. Barton now confesses, quite frankly, that there is scarcely a topic of importance in his earlier work—such, for example, as totemism, descent and marriage among the early Semites—upon which he has not had reason entirely to change his views.

Prof. Barton now attacks Hamitic and Semitic origins once more, moving on a wide front which embraces linguistics, ethnology, archæology, social anthropology and religion. In his view that the nations of western Asia were of a very mixed character, most prehistorians will concur, but they would also point out that the evidence upon which he relies is mainly linguistic and cultural, and does not necessarily imply wide differences in racial strain.

In regard to the origin of the Hamites and Semites, the view here put forward by the author

is that the Semites were one branch, the early Egyptians being another, of a stock which originated in North Africa, possibly in the Sahara They crossed to southern Arabia, and there developed their peculiarly Semitic characteristics A later fission led to the further differentiation of the northern Semites, who are usually regarded as the purest representatives of the race The occurrence of a strong brachycephalic element in the southern parts of the peninsula is held by Prof Barton to be due to the fact that this territory long served as a passage-way for commerce and racial movement, so that an alien element partially submerged the older dolichocephalic strain These are the brachycephals whom Sir Arthur Keith identifies as an intrusion of broad-headed people from the north, akin to, but not identical with, the Armenoid, holding that it is more nearly related to the broad-headed element, presumably from Central Asia, which appears in parts of India

In his racial and cultural analysis of early Mesopotamian civilisation, Prof Barton attaches much importance to what he characterises, somewhat vaguely, as a central Asiatic people, regarding the Sumerians as relatively late It is to be noted, however, that Dr Dudley Buxton, in his study of skulls from Kish, while recognising the existence of a broad-headed element in the early population, has expressed doubts as to whether the brachycephals from the Asiatic highlands penetrated the Mesopotamian area to any great extent in the earlier phases of its civilisation In attributing the prehistoric culture of the Indus valley to his central Asiatics, Prof Barton seems to ignore the trend of evidence which points in an increasing degree to a cultural connexion with western Asia

In dealing with social and religious origins, Prof Barton traces further the differentiation between the early Egyptians and the Semites He shows how the peoples, or rather tribes, who entered the Nile valley when driven from what is now the Sahara by desiccation, brought with them animal cults and totemic beliefs, which afterwards developed into the various animal cults of the Egyptian nomes and later into the Egyptian pantheon The Semites, on the other hand, elaborated as the characteristic expression of their beliefs a fertility cult, of which the central motive was the union of the male and female deities and its principal observance two seasonal festivals, one in spring and the other at harvest The institution of temple prostitutes and cognate observances, once interpreted by the author as evidence of an early state of sexual promiscuity and polyandry, he now accepts as part of the fertility cult In following Sethe's recent work on the totemic character of the cults of the Egyptian nomes, the author adopts a view which was advocated by Andrew Lang many years ago and accepted by the late Prof A H Sayce, though this fact is not noted

The interest of Prof Barton's work in its reference to the racial problem has precluded detailed consideration of his study of questions relating to other aspects of social institutions and religious beliefs In particular, his views on the origin and development of the Yahweh cult and the growth of monotheism among the Hebrews tempt discussion which space does not permit

Unfortunately, it is necessary to close on a note of criticism In dealing with the argument from physical anthropology, Prof. Barton fails to maintain the level of his scholarship in other fields It cannot be said that he has mastered his material, nor does he appear to be acquainted with the most recent literature, such as, for example, Buxton's later work on the material from Kish and Miss Garrod's more recent results which reveal a population of mesolithic age in Palestine resembling the predynastic Egyptians Misprints and errors in this section of the book are innumerable "Meyers" for Myres, "Sir *Charles* Keith", "Borm" for Bornu, and "Miss Caton-Thompson" when Miss Garrod is intended, may be slips, but they suggest a lack of the familiarity with the literature, necessary for a study of this character, which would correct them almost automatically

Standard Analytical Reagents

'Analar' Standards for Laboratory Chemicals being Improved Standards for the Analytical Reagents formerly known as 'A R' Pp xvi+295. (London British Drug Houses, Ltd, and Hopkin and Williams, Ltd., 1934)

IN 1914, when chemists found themselves deprived of the usual Continental supplies of laboratory reagents, a joint committee appointed by the Institute of Chemistry and the Society of Public Analysts drew up specifications to ensure a sufficient degree of purity in eighty-eight chemicals of importance in analytical work Reagents of this quality were distinguished by the letters "A R". This useful action was taken merely as a War-time emergency measure, and has not been continued by the two societies.

The letters "A R." acquired considerable prestige in this connexion and it is unfortunate that, as is implied in Prof J. F Thorpe's interesting foreword to this book, they should have lost their original significance by uncontrolled extension of their application. Chemists are not entirely without a remedy for this state of things. The British Pharmacopœia 1932, and the British Pharmaceu-

tical Codex 1934, between them provide standards for practically all the materials used in medicine These include a large number of chemicals and it is only necessary to add the letters "B P" or "B P C" to a requisition for one of these products to obtain it of the standard quality Specifications for chemicals of industrial importance are also being gradually produced by the British Standards Institution and the few so far dealt with can be obtained of the prescribed quality by use of the letters "B S S" Chemists might do worse than familiarise themselves with these three sets of authoritative standards and make use of them, where they meet their requirements

These standards do not, however, cover the whole field, and there is still need for a modernised and extended set of specifications corresponding to the original "A R" list Thus, the growing importance of micro-methods of analysis and the improvements in technique, which make it possible to determine with reasonable accuracy small fractions of a milligram, are creating entirely new requirements, both in kind and quality of analytical reagents For such work it is all-important that the operator should know the degree of purity of each reagent he has to use

This kind of information is provided for two hundred and twenty chemicals in the book before us The more important physical properties of each product are recorded, the methods of assay and the processes used for the determination of impurities are given, briefly, but with ample details, and the maximum limits of all likely impurities are stated The two firms concerned are well known as makers of laboratory chemicals and have each published books of specifications for these products They still manufacture independently, but have pooled their technical information and unified their methods of analysis and their specifications for the chemicals dealt with in this joint publication, an enterprise on which they are to be congratulated They have also registered jointly the trade-mark "Analar" to distinguish the products they manufacture in conformity with these specifications This action protects both the manufacturer and the consumer against the kind of deterioration which is said to have overtaken the standards implied by the letters "A R"

Short Notices

This Modern World and the Engineer Pp 140+18 plates. (Edinburgh Royal Scottish Society of Arts, 1934) 5*s* net

A GROUP of five distinguished engineers and one equally distinguished physicist has given us a concise and popular, although none the less authoritative, account of modern developments and trends in engineering The book is essentially a presentation of the Keith lectures for 1933 of the Royal Scottish Society of Arts With one exception, the authors are professors in the University of Edinburgh, hence the lectures "may be said to express the views of the Edinburgh School of Engineering on the tendencies in the several branches they treat" Prof C G Darwin, Prof A R Horne, Sir Thomas Hudson Beare, Prof F G Baily, Dr R Lessing and Prof H Briggs survey the fields of physics and of mechanical, civil, electrical, chemical, and mining engineering, showing us, with apt illustration, how directly and completely life in this modern world depends for its very existence on mechanism and its human control

This volume, however, does more than offer information; it places before us some of the world's major social problems, and leaves the layman—What more ingratiating way of evading responsibility has been discovered than this of calling one's self a layman?—with a brainful of thoughts to weave into his economic and political creed Prof. Briggs, in his "Extrapolation", shows that present-day engineering rests on a non-ethical basis, but he calls upon the engineer to consider questions of rights and consequences, and at a stride to identify himself professionally with his responsibilities as a civilised human being The engineer could make war difficult by disqualifying from membership of powerful professional institutions all connected with the manufacture of arms Organised control of industry could classify new inventions or processes as work-making or work taking, and exploit them accordingly for the greatest good Estimates relating to such processes should include consequences arising outside the factory walls These and other matters which are presented for our thoughtful consideration remind us how illusory is the barrier now between technology and sociology

A. A. E.

A Soldier in Science the Autobiography of Bailey K Ashford Pp v+425+4 plates (London George Routledge and Sons, Ltd, 1934) 12*s* 6*d* net

COL BAILEY KELLY ASHFORD, of the United States Army Medical Service, died on the day on which his autobiography was published His work in scientific medicine falls into two main parts, hookworm and sprue In 1899 he found hookworm eggs in the fæces of anæmic Porto Rican peasants, and by mass deworming lowered the island's mortality from anæmia by 85 and increased the peasant's working capacity by 60 per cent He recognised that the worm was not the well-known Old World hookworm, but it was left to Stiles to designate it *Necator americanus* In 1933 Ashford illuminated acute hookworm infection by his description of a small epidemic acquired during sea bathing During the War his main charge was the command of the school at Langres for the battle training of American medical

officers He was awarded the D.S M and Honorary C M G, and the Grand Cordon of the Order of the Nile, and was appointed editor-in-chief of the United States Medical History of the War He was instrumental in founding in Porto Rico an Institute of Tropical Medicine and Hygiene, and in arranging for its expansion into a School under the auspices of the Columbia University, New York After experience of 4,000 cases of sprue he concluded that the essential factor in its causation was unbalanced diet, and that when to this was added infection by *Monilia*, of which he recognised only one species, there resulted sprue He unswervingly advocated and fruitfully practised that combination of clinical observation and scientific investigation which has strikingly advanced tropical medicine CLAYTON LANE

Thoughts of a Schoolmaster (or Common Sense in Education) By H S Shelton Pp 256 (London. Hutchinson and Co (Publishers), Ltd, n d) 6*s* net

THE strength of this book lies in the rich variety of its author's experience As a boy he was in four schools, and as a master in twenty five, including public, grammar, co educational, private, proprietary and technical schools Not that by nature he was a 'rolling stone', but that by necessity he was transferred from place to place during the War He deals only with secondary schools, and he touches many topics, including the 'unpopularity' of schoolmasters, the tradition of the headmaster, salaries, co education, discipline and so on, and whether one agrees with him or not, his criticism is always practical and to the point, and it is often constructive.

On the subject of science teaching, Mr Shelton condemns the general neglect of biology, and suggests, as a practicable reform, advanced courses in biology, with interchange between neighbouring schools, and special attention to biology in country schools He pleads also for universal courses in general science, not, however, made up of scraps of chemistry and physics and biology and geology and astronomy merely strung together, but conceived as a single subject with many interrelated divisions. The author is not, and probably does not claim to be, free from the charge of dogmatism But he writes with knowledge, at a time when our secondary school system is very far indeed from being above criticism.

The Principles and Practice of Surveying By Prof C B Breed and Prof G L Hosmer Vol 2 *Higher Surveying* Fourth edition Pp xix + 603 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1934) 21*s* 6*d*. net

ALTHOUGH this work is an American publication, it deals with its subject in such a way as to be as suitable to students as most of the well known English books thereon It is extremely well set out and lucid in style, and includes such modern developments as those of geology in relation to topography, and aerial photography as applied to surveying A most useful set of problems is appended at the end of each section, but it is unfortunate that the answers to these are not given

With the increasing use of precise levels, fuller details relating to the parts of such instruments could have been given with advantage, while the reproduction of the photographic illustrations is not up to the standard of the letter-press It would not be usual in Great Britain to expand the portions relating to the flow of water in channels to so great an extent, these constituting a chapter generally found in large works on hydraulics.

The size and method of binding is evidently designed for field use, in its general tenor, the work can be confidently recommended to students who are preparing for engineering degrees of honours standard, and to all who are interested in the subject.

B H. K

Progress of Archæology By Stanley Casson Pp. xii + 111 + 24 plates (London G Bell and Sons, Ltd, 1934) 6*s* net.

MR CASSON surveys progress in archæological discovery during the last fifteen or twenty years throughout the world, dividing it into nine main archæological provinces His purpose is to touch upon the most significant discoveries or excavations in each and to bring out, where such consideration is appropriate, their interrelation Mr Casson's book is pleasantly and easily written and well illustrated; but on even the most generous interpretation of the lines upon which a book of this kind can be written for an educated but non-technical public, it is far too sketchy The treatment of Africa, even including Egypt, and of America, for example, is quite inadequate, in view of recent work in both continents The first chapter, on the aims and methods of archæology, is by far the best, though it shows some confusion of thought, and the definition of the field of archæology not only begs the question, but also is contradicted by the pages which immediately follow.

Practical Plant Anatomy: an Elementary Course for Students By Comyns J. A Berkeley Pp 112 (London: University of London Press, Ltd, 1934) 3*s*

A GOOD practical guide to elementary botany is sorely needed, and this book by Mr. Comyns Berkeley will fill part of the gap, the practical plant anatomy is dealt with, and this is done extremely well. The author is obviously conversant with the practical side of botanical study, for he not only gives clear directions as to methods of approach but he also gives hints of difficulties—sometimes slight, but irritating—that are constantly cropping up. Another problem that students and even teachers are constantly meeting is that of sources of material. Few books give the reader any idea of where to obtain their type specimen Mr. Berkeley gives sufficient help in a series of tables. This is very useful.

It is a pity that the author did not go a little further and cover completely an intermediate science course in botany.

Immigration of Insects into the British Isles

By Dr. C. B. Williams, Chief Entomologist, Rothamsted Experimental Station

ABOUT a hundred years ago, it was gradually dawning on British entomologists that many of the butterflies in this country might be immigrants from abroad. Among the species first suspected of this habit were the Clouded Yellow (*Colias croceus*) and the Pale Clouded Yellow (*C. hyale*). It is curious that about the same time a more practical controversy was commencing in the United States as to whether one of their most serious pests, the cotton worm (*Alabama argillacea*) was a permanent resident of that country, or not. To-day we know that not only these early disputed species, but also many other Lepidoptera, dragonflies, and some members of other groups of insects, regularly migrate, and that in a number of cases these movements come to an end in the British Isles, thus giving the insects in question the status of 'immigrants'.

In the study of migration it is possible to start from two points of view. We may study a single insect throughout the whole range of its migration. An example of this is seen in an account that I gave of the migration of the Painted Lady butterfly (*V. cardui*) in NATURE of April 11, 1925 (p. 535). This is, in my opinion, the most fruitful method of investigation. The alternative is to study the migration phenomena of all insects as seen within a limited area. By this method it is easier for a single investigator to take field observations, and easier to obtain the co-operation of voluntary helpers, but it must always be remembered that the results are only a group of incomplete phenomena, the basic causes of which must often be sought elsewhere.

Most insect migrations in temperate zones consist of movements in the spring from sub-tropical or warmer zones towards the cooler parts of the temperate zone with—sometimes at least—a return southward in the autumn. Since the British Isles are in the cool temperate zone, it follows that they will figure chiefly as an end point for spring migrations and perhaps, more rarely, as a starting point for autumn movements.

Among the insects which come into Great Britain in this way in the spring are to be reckoned about twelve of our sixty-six butterflies, about half our Hawk moths (Sphingidæ), quite a large number of other moths, including even some Tineidæ less than an inch across the wings; at least a dozen of our dragonflies, and an occasional errant locust. It may also be necessary to add to the list certain Coleoptera, Aphidæ and Syrphidæ (hover flies), which are occasionally washed up in great numbers on our shores after a storm, but at the moment the evidence is too fragmentary to distinguish between wilful migration and accidental distribution by wind.

Some of these species do not breed at all in Great Britain, some breed only during the summer and die out each winter, while others breed regularly and continuously here, but are reinforced at intervals from abroad. Some immigrants arrive regularly each year, while others come only at intervals of several years, or in very varying numbers. Many only invade our southern shores and the counties along the coast; others, especially in years of great abundance, may spread as far as the north of Scotland and the Orkney and Shetland Isles. Some cross the English Channel conspicuously by day in large bands, whilst others appear to cross by night or individually and have never been recorded actually during the movement.

Turning in more detail to what is known of some of the species: five of our immigrant butterflies, the Monarch (*D. plexippus*), the Camberwell Beauty (*V. antiopa*), the Bath White (*P. daplidicæ*), the Long Tailed Blue (*L. boeticus*) and the Queen of Spain Fritillary (*A. lathonia*) do not breed in Great Britain; the Clouded Yellow (*C. croceus*), the Pale Clouded Yellow (*C. hyale*), the Painted Lady (*V. cardui*) and the Red Admiral (*V. atalanta*) breed regularly during the summer but seldom, if ever, survive a winter: while the three Cabbage White butterflies (*Pieris brassicæ*, *rapæ* and *napi*) are regular residents as well as irregular immigrants.

Most of these butterflies come to us from the more southerly parts of Europe in the spring or early summer, but there are some exceptions to this rule. The swarms of Cabbage White butterflies appear to originate in the Baltic area and fly about midsummer southward through Germany and westward across the North Sea and the Netherlands. The Camberwell Beauty arrives almost exclusively in the autumn along our eastern shore, even as far north as Inverness, and probably comes from Scandinavia. The Monarch butterfly is unique in coming to us in the autumn from the west across the Atlantic. In the United States at that time of the year enormous flocks are migrating southward, and our immigrants are probably wanderers blown out of their path and helped across by the prevailing westerly winds.

Finally, the Painted Lady comes to us from the south, but there is reason to believe, as already pointed out in my earlier article in NATURE, that our immigrants may come from as far afield as North Africa, if not farther.

Among the Hawk moths, the Death's Head (*A. atropos*), the Oleander Hawk (*D. nerii*), the

Silver-Striped (*C livornica*), the Striped Hawk (*H celerio*), the Convolvulus Hawk (*H convolvuli*), the Bedstraw Hawk (*C galii*), the Spurge Hawk (*C euphorbiæ*) and the Humming-Bird Hawk (*M stellatarum*) are all immigrants which do not normally survive the winter in Great Britain, though most of them may breed during the summer of immigration The status of the Privet Hawk and the Pine Hawk is not definitely settled All the immigrants come from the south, but practically nothing is known of their origin except that some most certainly reach their maximum abundance in early spring in North Africa

Information about the smaller moths is scattered and uncertain Definite immigrants include the Silver Y moth (*Plusia gamma*), the Rush Veneer (*Nemophila noctuella*), the Satin moth (*L salicis*), the Crimson Speckled (*D pulchella*) and many others The Diamond Back moth (*P maculipennis*), a small but serious pest of crucifers, is believed to cross the North Sea, while one of the most widely distributed pests of cotton, the American Boll Worm (*Heliothis armigera*), is a rare immigrant in Great Britain, where it boasts of the popular name of the "Scarce bordered Straw"

The British dragonflies include a dozen immigrants, all belonging to the Anisopteridæ Some of these are only very rare wanderers, others, such as *Sympetrum fonscolombii*, *S flaveolum* and *S sanguineum*, are more regular immigrants, while *Libellula depressa*, *L quadrimaculata* and *Aeschna grandis* breed here regularly and are also immigrants at times No member of the family Zygopteridæ has yet been considered an immigrant in Great Britain

Apart from the details of which insects migrate, when they migrate and where they start from, there are a number of general problems connected with this subject, chief among which is the question of a return flight or emigration in the autumn towards the south in those species which arrive from the south in the spring Until recently, there was little evidence in support of this, and zoologists were inclined to think that insect migration was therefore fundamentally different from that of birds However, little by little, evidence is accumulating that makes it seem that a return flight, at least of some species, does take place Particularly is this so in the case of the Red Admiral butterfly (*V atalanta*) for which we have now quite a number of records of small autumn movements to the south on our shores, while in the case of *V cardui* an ornithologist has reported their arrival on several occasions on the North Egyptian coast at dawn, flying in from across the Mediterranean along with the migrating quail. It is important to recognise, in collecting evidence on this point, that a migration need not be a gregarious action, and we know of one butterfly, the Monarch of North America, which carries out a movement in one direction gregariously and in the reverse direction individually

Other problems requiring solution, which can only be settled by long continued collection of facts, are the reasons why one or other sex (more often the male) should frequently predominate in a flight, or if there is any periodicity connected with the movements, and how the insects keep to their fixed direction On the last point there seems to be not the slightest clue, but it might be as well to point out that the evidence in hand lends no support to the oft-quoted theory that insects fly at a definite angle to the wind Flights, on the whole, are as often with the wind as against it, and while there are one or two cases known of a change of wind resulting in a change of flight direction, there are very many more records of flight direction remaining constant in spite of frequent changes of wind

In the past, the collection of records on the immigration of insects into Great Britain has been entirely haphazard Scattered through the pages of a dozen entomological and natural history journals of the past century are records of sudden abundances, unexplained absences and occasionally of clouds of butterflies crossing the English Channel or arriving on the shores of Great Britain But the absence of records for several years means little or nothing but a period of lack of interest However, a little more than three years ago the South-Eastern Union of Scientific Societies formed an Insect Immigration Committee under the energetic secretaryship of Capt T Dannreuther This Committee has organised a widespread system of district recorders, has issued a list of insects about which information is specially needed, and has sent out some thousands of standard record cards to voluntary observers in all parts of the country The results have so far surpassed expectations, and have thrown new light on the movements of certain butterflies, particularly the Common Whites and Red Admiral Now also the Committee has obtained, by permission of the Trinity Brethren, the co-operation of a number of keepers of light-ships and light-houses round the coast, and the records they are sending in are adding to our knowledge of many previously known migrants, and suggesting new and unexpected insects that will require watching in the future

The study of insect migration in Great Britain is now better organised than it has ever been before, and far more completely than anywhere else in the world; but many additional helpers are needed, and years of work and co-operation from the Continent will be necessary before a definite answer can be given to any of the outstanding problems

Institution of Electrical Engineers' Library of Sound Films

THE Institution of Electrical Engineers is collecting a library of sound films made by eminent electricians and electrical engineers It is hoped that they will be of interest not only to subsequent generations but also to many local centres of the Institution overseas Sound films have already been taken of Sir J J Thomson, Sir Ambrose Fleming, Mr W M Mordey and others After being introduced by the president of the Institution, the speaker makes a short address giving a review of the progress made in electrical science or engineering from his earliest days and sometimes trying to foretell the trend of development in the future We have pleasure in printing below the address given by Sir Oliver Lodge for this library

---

I have lived from the very beginning of the electrical age that is now upon us When I was young there was no such thing as a dynamo If we wanted a current of any magnitude, say for instance to supply an electric arc, we had in those days to mess about with a Grove's battery, consisting of zinc, platinum and acids, and it was a troublesome business I remember that the name 'dynamo' was invented by Lord Kelvin in a paper before Section A of the British Association, when I was a secretary to that body

I remember seeing the original Pacinotti machine, which soon developed into the Gramme armature, and then ingeniously the Siemens firm introduced a double-winding and made the modern Siemens armature, there had been an old Siemens armature, with an iron rail wound longitudinally, which was shown at the 1862 Exhibition producing strong currents, and exciting much interest It was no easy matter to get a really strong current in those days covered wire was almost a novelty, while to make connexion between different things there was no notion of plugging in two terminals, we had to screw up each wire with a binding screw, a pair of binding screws were the only terminals

I remember the first electric lamp shown to the Telegraph Engineers by Mr (later Sir Joseph) Swann, which he said would serve well for a reading-lamp, and not require any matches for its lighting up And a little later I remember Colonel Crompton coming for one of the conversaziones at University College, London, and bringing a number of such lamps, which he arranged in the entrance hall, festooning them as an exhibition He came himself and superintended the erection with extraordinary energy, taking possession of Carey Foster's laboratory, and having it all rigged up in time

I remember too the first visit of Graham Bell and his demonstration of the telephone at South Kensington, when he lectured to the Physical Society in a most beautifully articulate manner, pronouncing everything completely and accurately He was just the right type of man to make a metal disc speak

Then Hertz made a great advance, he discovered how to produce and detect waves in space, thus bringing the ether into practical use, harnessing it for the transmission of intelligence, in a way which has subsequently been elaborated by a number of people

Now, this present century, which has made many undoubted discoveries in physics, seeks to discredit and deny the ether of space, and I want to conclude this talk by a few words upholding its reality It is the ether which conveys waves in the fraction of a second to the antipodes, it is that which brings us information from the stars and the most distant nebulæ, which otherwise we should be without The ether is the seat of all radiation energy and indeed of all other energy, whether it be in the form of light or other waves I remember when the nature of light was not known Clerk Maxwell's great paper dated from the year 1864 or maybe '65, when I was just leaving school and was not awake to its magnificence I did not know of it till the 'seventies, but in 1873 his great book on electricity appeared, and that year I attended my first meeting of the British Association, at Bradford, and heard it spoken of This was a book worthy to be mentioned in the same breath as the "Principia"

Newton and Maxwell are among the glories of the human race and they did for the ether something magnificent which has not been surpassed by any work of man The ether is the vehicle of gravitation and of light Its theory is not complete even yet We are still groping after their great and unfinished discoveries Einstein has shown us something more about gravitation, and has done away with action at a distance, and Planck has discovered the law regulating the interaction of ether and matter, so that radiation is only produced and destroyed in discontinuous quanta. But interference shows that radiation and the ether are continuous in free space, and that quanta only make themselves evident at the beginning and end of radiation—at the generation and absorption of light—when the ether is associated with the discontinuous thing that we call matter.

I have here indicated what will be the work of the twentieth century, to complete the theory of the ether and to show how all things lead to an intelligible and concrete reality, very different from the abstractions and confusions under which we now, for the time, labour Yet the present is a phase through which we had to go it is an intermediate era in physics, through which we are guided by great men, Eddington and Jeans and Dirac, men who are contributing a great deal to physics and astronomy, work which we could not do without, and which forms a necessary avenue to the clear open space beyond

Before the end of the twentieth century, as I think, or at any rate in the twenty-first, the ether will be recognised as the one means of communication between the atoms, and the whole of physics will become once more luminous and clear, constituting a glorious epoch for our descendants The ether will come into its own again, not only for practical purposes as the seat of all potential energy, but with a clear understanding of it as the one substance that holds the universe together, in which all matter is embedded, without which even locomotion cannot be properly understood, and which constitutes the physical vehicle for life and mind OLIVER LODGE

Scientific Centenaries in 1935

By ENG CAPT EDGAR C SMITH, O B E, R N

GLANCING back once again over the history of science during the last few centuries with the object of recalling those men of science whose centenaries occur during the coming year, it is but natural to turn to the early records of the Royal Society

In these, over and over again, is found the name of Robert Hooke, who was born on July 18, 1635, three hundred years ago A scholar of Westminster School and a graduate of Christ Church, Oxford, he became the friend of Willis, Boyle, Wilkins, Seth Ward and others On November 12, 1662, he was appointed curator of experiments to the Royal Society and on June 3, 1663, was elected a fellow of the Society Two years later he was made professor of geometry in Gresham College, and it was in his apartments in Gresham's old mansion in the City of London that he passed the greater part of his life A long list of papers and experiments testify to his ingenuity and versatility, and no doubt in due course tribute will be paid to his memory "As to his Person," said Benjamin Martin in his "Biographia Philosophica", "he made but a mean Appearance, being very small and somewhat crooked, but he had an active, penetrating, indefatigable Genius, sparing no Pains in Quest of the Truth in Relation to whatever came under his Consideration " Hooke died on March 3, 1703 and was buried in St Helen's Church, Bishopgate, a church which probably has more associations with the Royal Society than any other

Two contemporaries of Hooke's abroad were Johann Becher (1635-1682) and Christoph Sturm (1635-1703) Becher was one of the first chemists to cast off the mystical language of the alchemists, and in his writings can be found the germ of the phlogiston theory He wrote much, travelled widely, and only a short time before his death came to England to visit the Cornish mines Sturm, who was also a German, was professor of physical science in the University of Altdorf, and is remembered as an advocate of the teaching of science in schools In their day, Germany was slowly recovering from the inconceivable miseries of the Thirty Years War, during which, it is said, the population fell from 20,000,000 to 4,000,000

It was in 1635 in the midst of that war that Wilhelm Schickard (1592-1635) and Johann Faulhaber (1580-1635) died The latter was an able mathematician who was acquainted with Descartes, while the former was known to Kepler and to Gassendi It was to Gassendi that Schickard sent his observations of the transit of Mercury of 1633

The work of these scientific worthies belongs almost entirely to the seventeenth century, a period during which, says Cajori, the progress of physics was truly extraordinary During the eighteenth century, he says, physics proper was cultivated by men of more limited powers than those of Galileo, Huygens and Newton For all that, however, there was great activity in various branches of science, especially in mathematics and astronomy, and in England practical astronomy made wonderful advances.

To these advances a succession of clever mechanicians contributed, and of all the British men of science born two hundred years ago none has a more interesting record than Jesse Ramsden (1735-1800), who from a clothworkers' apprentice at Halifax rose to be the leading instrument maker in London "Esteemed by the great, cherished by his friends and loved by his servants and workmen", Ramsden was called by Delambre "le plus grand de tous les artistes". From Ramsden's shop in Piccadilly came some of the finest telescopes and theodolites He was elected a fellow of the Royal Society in 1786 and nine years

later was awarded the Copley Medal for his "Various Inventions and Improvements in Philosophical Instruments" Another instrument maker of note was John Coventry of Southwark, who was born in the same year as Ramsden but outlived him by twelve years

The year 1735 also saw the birth of Gregorio Fontana (1735–1803), for many years a professor of mathematics at Pavia and Milan, of Charles Auguste Vandermonde (1735–1796) the French mathematician and chemist who had much to do with founding the Conservatoire des Arts et Metiérs, of Hugh Williamson (1735–1819) of Philadelphia, who was one of the observers of the transit of Venus of 1769, and also of the chemists Keir and Bergmann

James Keir (1735–1820) began life in the army, but in 1768 settled at West Bromwich and devoted himself to chemistry, geology, glass-making and the writing and translation of scientific works He was a friend of Erasmus Darwin, Watt, Boulton and Priestley, joined in the monthly meetings of the Lunar Society, and from 1785 onwards was a fellow of the Royal Society Tobern Olof Bergmann (1735 1784) was for a long time professor of chemistry at Uppsala "He was," said Senier, "the first to perform chemical analysis systematically and laid the foundation of that art" At his death the Academy of Sciences of Stockholm had a medal struck to commemorate his work

Bringing the survey a century nearer to our own time, to the year 1835, there is a considerable list of deaths and a longer list of births to be recognised This part of the survey may well begin with Edward Troughton (1753–1835) who, like Ramsden, came from the north to achieve distinction as a London instrument maker He also was a fellow of the Royal Society and a Copley medallist His shop was in Fleet Street, and astronomical instruments of his making went to Greenwich, Paris, the Cape, Cracow, Brussels and elsewhere Airy described Troughton's mode of graduating arcs of circles as "the greatest improvement ever made in the art of instrument making"

Astronomy is also represented by Dr John Brinkley (1763–1835) sometime Bishop of Cloyne Born in Suffolk, he was senior wrangler in 1788 and four years later became Andrews professor of astronomy in Trinity College, Dublin. He also became the director of Dunsink Observatory and was the first Royal Astronomer of Ireland

Another Copley medallist who died in 1835 was Capt Henry Kater, one of the earliest workers on the trigonometrical survey of India Ill-health brought him back to England and after further service in the Army, in 1814 he was placed on half-pay, from which time he devoted himself to science He was well known for his accurate pendulum experiments and his study of standard weights and measures, and, had his life been prolonged, his services would undoubtedly have been used in connexion with the replacement of the British standards destroyed in the burning of the Houses of Parliament in October 1834

Physics is also represented by Leopoldo Nobili (1784–1835) of Florence, who invented the thermopile afterwards used with great skill by J D Forbes and Melloni

To this record of men of science who passed away a century ago may be added the Irish geologist, John MacCulloch (1773–1835), who abandoned medicine for the study of the rocks and became geologist to the Trigonometrical Survey, Gilbert Thomas Burnett (1800–1835), the short-lived professor of botany in King's College, London, the great French surgeon Baron Guillaume Dupuytren (1777 1835), who from the humblest ranks raised himself to the position of the foremost surgeon in Europe, but, falling sick, refused to permit an operation upon himself, preferring as he said rather to die at the hand of God than of man, Thomas Charles Auguste Dallery (1754–1835), a French pioneer of steam navigation and screw propulsion, and lastly Sir Edward Banks (1769–1835), who with his partner, William John Jolliffe (1774–1835), built Waterloo, Southwark and London Bridges, and was the principal contractor of his day

As the frontiers of science are extended, and its territories enlarged, so does the number of explorers ever increase Of those who have made notable contribution to science and have passed away in recent times, the columns of NATURE, since its foundation in 1869, contain biographical sketches of many hundreds, and by the aid of these it is possible to recall briefly some of the outstanding men of genius and talent who were born a century ago Foremost among these, perhaps, must be placed the distinguished American astronomer, Simon Newcomb, who was born on March 12, 1835, and died on July 11, 1909 Loewy, writing in NATURE of May 4, 1899, said. "Newcomb must be considered without contradiction as one of the most celebrated astronomers of our time, both on account of the immensity of his work and the unity of view which marks the choice of the subjects treated by him".

Two days after Newcomb was born in Nova Scotia, Giovanni Virginio Schiaparelli, the Italian astronomer, was born in Piedmont Schiaparelli died just a year after Newcomb, on July 4, 1910. The English astronomer, Sir William Huggins, had only recently passed away and on July 5, 1910, the *Times* wrote, "As Huggins stood at the

head of English-speaking astronomers, so Schiaparelli stood at the head of the astronomers on the Continent"

Another astronomer who was born a century ago was Friedrich August Theodor Winnecke (1835-1897), whom Sir David Gill called "the greatest teacher of practical astronomy since the days of Bessel", and another, Jean Charles Rudolphe Radau (1835-1911), who though German by birth spent most of his life in France and at the time of his death was a member of the Paris Academy of Sciences and the Bureau des Longitudes

Chemical science of the nineteenth century is represented by Adolph von Baeyer (1835-1917), August Dupre (1835-1907), Rudolph Fittig (1835-1910) and Johann Wislicenus (1835-1902) All were of German birth, but Dupre became a naturalised Englishman and as such held important Government posts Fittig, von Baeyer and Wislicenus all received the Davy Medal of the Royal Society One of Fittig's earliest appointments was to the University of Tubingen, and it was in 1871 that Sir William Ramsay, then a youth of nineteen wrote home "I go regularly to Fittig's lecture at 8 He lectures very distinctly and clearly It is really very beautiful to see the way the organic compounds are arranged" Of the career of Wislicenus, and of the charm of his character, much is contained in the memorial lecture delivered in 1905 to the Chemical Society by W H Perkin, Jr

The progress of science is furthered by many means, and this is illustrated by comparing the careers of the three physicists Joseph Stefan of Austria, Elisha Gray of the United States and George Carey Foster of University College, London, who were all born in 1835 Stefan by his researches furthered our knowledge of liquids and gases, light and sound and electricity, and his name is now recalled by the Stefan-Boltzmann law of radiation Gray was a practical electrician with more than sixty patents to his credit, and though originally a professor he was afterwards connected with manufacturing It will be remembered that on February 14, 1876, he lodged a caveat for a telephone with the American Patent Office only a few hours after Alexander Graham Bell had visited the office on a similar errand Carey Foster, on the other hand, although a contributor to scientific literature, was known for the part he played in furthering the best interests of University College, in supporting the claims of women to university privileges and in extending the use of physical laboratories in the teaching of science

It need scarcely be said that this list of men of science born in 1835 who were devoted to physical subjects could be made longer, but it is perhaps unnecessary to do so Finally, therefore, attention is directed to the names of one or two distinguished naturalists whose centenaries occur this year Of these, Alexander Agassiz (1835-1910), the son of Louis Agassiz, was for a time superintendent of the well-known Calumet and Hecla Copper Mines, Lake Superior, but was best known for his work as a zoologist and oceanographer Born at Neuchâtel, Switzerland, he accompanied his father to the United States in 1846, and there he passed the remainder of his life, holding important positions and taking part in many scientific expeditions Another naturalist connected with North America was Joseph Frederick Whiteaves (1835-1909), who was born at Oxford and worked there under John Phillips. A visit to Canada in 1861, however, led to his studying the geology of Quebec, and he became palæontologist, zoologist and assistant director of the Geological Survey of Canada In 1907 he was awarded the Lyell Medal of the Geological Society of London Of Sir Archibald Geikie (1835-1924) it is but necessary to recall that he was in turn director of the Geological Survey of Scotland, Murchison professor of geology and mineralogy in the University of Edinburgh and director of the Geological Survey of the United Kingdom He was born on December 28, 1835 and died on November 10, 1924

Obituary

PROF B H BUXTON

BERTRAM HENRY BUXTON was the eldest son of Mr Charles Buxton, M P, of Fox Warren, Cobham, Surrey He was born in 1852 and was educated at Eton He entered the business with which his family was associated, but did not find it congenial Preferring travel, he was a frequent visitor to the United States, on one of his visits, medicine attracted him Having voluntarily undertaken duty on board a passenger vessel in quarantine because of cholera, he followed up his observations through the Health Officer of the Port of New York, who introduced Buxton to bacteriology At Cornell he studied in the Post Graduate Laboratory and rapidly became proficient His keen mind quickly appreciated medicinal science. The University gave him a doctor's degree, and finally he occupied the chair of bacteriology

Buxton's work was outstanding, his technique brilliant, no detail was too small for his scrutiny or attention He was among the first to recognise the differing strains of typhoid bacillus in culture; he made notable contributions to the study of erysipelas and typhoid fever, and at the Memorial Cancer

Hospital developed Dr Coley's vaccine of erysipelas for the treatment of inoperable sarcoma He made fine histological preparations and developed a remarkable skill in microscopic pathology and photomicrography He pursued these morphological studies until his voluntary retirement in 1912

Returning to Surrey, Buxton lived at the Manor House, West Byfleet, at the foot of the hill on which is situated his parental home From 1922 he worked as a guest in the laboratory of the Royal Horticultural Society With the late Dr F V Darbishire he studied the effect of varying hydrogen ion concentrations on the colour pigments of plants It was always a great pleasure to watch Buxton at work—so neat and precise in his methods, so keen was his observation of every colour change. His work with Darbishire was reported in the Royal Horticultural Society's *Journal* and in the *Journal of Genetics* Buxton was also keenly interested in genetics and he raised a cross between *Digitalis purpurea*, the purple foxglove, and *Digitalis ambigua* As the result of doubling of the chromosome complement, this hybrid became fertile and has now been recognised as a new species, *D mertonensis* He collaborated with the cytologists at Merton in these investigations, particularly with Dr C D Darlington and the late Dr Newton Other genetical work concerned the Wisley blue primrose and *Primula acaulis*

Buxton keenly felt the loss of his colleague Darbishire, who died in 1932, and his visits to the laboratory became more infrequent. A year or so ago he visited Devonshire and decided to live there He survived his brother Earl Buxton, who was a year younger, by two months Like him, he was also keenly interested in birds, and on his walks over the Surrey commons and in the woods he derived much pleasure from observing the pheasants and the antics of jays and activities of green woodpeckers His charm of manner and courtesy was shown to all, his modesty even prevented his colleagues from learning much of his earlier work, but his wide and varied research has established his reputation in two continents M A H T

WE regret to announce the following deaths:

Prof Arthur Brožek, professor of genetics in the University of Prague, known for his work on plant breeding, on November 8, aged fifty-two years

Dr Otto Folin, professor of biological chemistry in the Harvard Medical School, an authority on the technique of urine analysis, on October 26, aged sixty-seven years

Prof R Kovesligethy, professor of cosmography and geophysics in the University of Budapest, an authority on seismology, on October 12, aged seventy-two years

Miss Rosalie B J Lulham, lecturer in natural history at the Froebel Educational Institute, and author of "An Introduction to Zoology through Nature Study", on December 28

News and Views

New Year Honours

THE following names of scientific workers and others associated with scientific interests appear in the New Year Honours List *Baronet* Sir Holburt Waring, president of the Royal College of Surgeons *G C B* Sir Josiah Stamp. *K C M G* Lieut.-Gen Sir William Furse, director of the Imperial Institute, Dr A C D Rivett, deputy chairman and chief executive officer of the Council of Scientific and Industrial Research, Commonwealth of Australia *Knights* Dr C V Boys, for services to physics, Prof W Langdon-Brown, regius professor of physic, University of Cambridge, Dr E Deller, principal of the University of London, Dr. Cyril Fox, director of the National Museum of Wales, Dr J B Orr, director of the Rowett Institute for Research in Animal Nutrition, Aberdeen, Prof E B Poulton, honorary life president of the Royal Entomological Society of London, and emeritus professor of zoology in the University of Oxford; Dr J D. Sutherland, lately assistant forestry commissioner for Scotland, member of the Forestry Commission. *C.B* Col H. St J L Winterbotham, Director-General of Ordnance Survey, Ministry of Agriculture and Fisheries. *C.M.G.:* Lieut.-Col. C L. Carbutt, Chief Native Commissioner, Southern Rhodesia, Prof. F. L. Engledow, professor of agriculture, University of Cambridge, and member of the Colonial Advisory Council of Agriculture and Animal Health, Lieut.-Col S P James, medical officer and adviser on tropical diseases, Ministry of Health, and member of the Colonial Advisory Medical Committee *C I E* Rai Bahadur Daya Ram Sahni, Director-General of Archæology in India *C B E*. Dr. E J Allen, secretary of the Marine Biological Association of the United Kingdom and director of the Plymouth Laboratory; Mr C C Hawkins, lately superintendent of the Department of Technology, City and Guilds of London Institute, Dr J S Plaskett, director of the Astrophysical Observatory, Dominion of Canada *O B E* Mr G W Austin, principal scientific officer, R N Torpedo Factory, Greenock, Mr R W Harris, secretary of the London School of Hygiene and Tropical Medicine *M B E* Dr Alice E. Wilson, assistant invertebrate palæontologist, Department of Mines, Dominion of Canada

Heavy Water in Chemistry

THE lecture by Prof Polanyi which is published as a Supplement to this issue of NATURE directs attention to some of the applications which may be made of heavy water in elucidating the mechanism of chemical reactions The heavy water may be either the variety containing heavy hydrogen in place of ordinary hydrogen, or that containing heavy

oxygen in place of ordinary oxygen, and the distribution of the heavy atoms among the products of reactions will indicate the part played by water in them The striking difference in chemical properties between heavy hydrogen and ordinary hydrogen is due very largely to the differences in zero-point energy, which Prof Polanyi calls permanent energy, the existence of which is predicted by the new quantum theory It is possible to calculate this energy, and the results of the calculations may be checked by measurements of equilibria in which the two sorts of hydrogen participate These experiments are in agreement with the theory Exchange of heavy hydrogen from heavy water may occur with other compounds, such as benzene, and the mechanism of hydrogenation in ordinary reactions can also be followed in such experiments The use of nitrogen and carbon isotopes is likely to prove important in the future

Future of the Sulphur Industry

A PAPER by M P Applebey, published in *Chemistry and Industry* of December 28, on recent developments in the chemistry of sulphur, foreshadows important advances and perhaps far reaching changes in those industries which are concerned with sulphur and its oxide Researches extending over some years in the laboratories of Imperial Chemical Industries, Ltd, at Billingham have solved the problem of concentrating sulphur dioxide from metallurgical gases containing from three to seven per cent, by the ingenious method of using a sulphite bisulphite system which can be regulated to have a moderately high *p*H in the cold and a much lower one when hot by the addition of a substance such as aluminium chloride, the hydrolysis of which is much increased by rise of temperature It has been further discovered how to reduce the practically pure sulphur dioxide so obtained by coke

$$SO_2 + C = CO_2 + S$$

The reduction takes place very rapidly and almost completely at 1100° C and is exothermic It is considered possible to convert economically the sulphur dioxide in dilute furnace gas on the large scale into sulphur, and since this can be transported at about a tenth of the cost of sulphur dioxide and a fifth of the cost of sulphuric acid, the process may be expected to alter radically the economic aspect of sulphur dioxide disposal

THE metallurgical industries are at present forced to make sulphuric acid to get rid of the sulphur dioxide they produce, and the disposal of this acid locally causes great difficulty, and limits the size of the smelting plants All these troubles will largely disappear if sulphur is produced instead at one centre. Dr. Applebey visualises a new rationalisation of the metallurgical industries based on pyrites which will enable the sulphur, the non-ferrous metals and the iron to be separated at or near the port of arrival. With the new process, the manufacture of sulphur from anhydrite or gypsum becomes practicable, and lastly, the process reopens in a much more favourable manner the perennial question of the possibility of recovering the sulphur from coal. The discoveries outlined are probably the most important which have been made in the heavy chemical industries for some considerable time.

The Christmas Day Empire Broadcast

FOR the third year in succession, the British broadcasting programmes on Christmas Day included a special hour during which greetings were exchanged with various parts of the world This year the major portion of the programme came from the countries of the Empire, the Dominions, India and Southern Rhodesia each contributed one or more scenes representing different phases of their national lives Twenty-five different scenes were presented, and the programme was notable for the accuracy of the timing and the rapidity with which the various connexions were made in succession It was not a steady tour round the world as was the case on a former occasion, rather had it the air of a random selection of individuals in such places as Australia, Ireland, South Africa, Canada and so on A broad outline of the technical arrangements by which the programme was carried out was given in the issue of *World Radio* of December 21 In order that so many different programme sources may be blended together to form a homogeneous whole, rapid and silent switching arrangements must be provided by means of which each item may be faded into the next without a break This is made possible by the dramatic control panel, which was originally designed by the B B C to provide silent and speedy switching between a number of studios in a production of a radio play It is a simple step to adapt the use of such a panel to the switching of long distance telephone circuits, whether these be land line or radio

FOR the purpose of the Christmas Day programme, control of fifteen channels was required, and for this purpose a recently developed dramatic control panel was brought into action at Broadcasting House. The panel is so long that it has been necessary to provide a sliding seat for the producer to keep all the controls within reach The collection of the individual items of the programme was made along circuits connecting Broadcasting House with the Post Office International Telephone Exchange at Faraday Buildings This exchange is connected with the radio telephone transmitting and receiving stations at Rugby and Baldock respectively, which daily handle the normal commercial radio telephone traffic with all parts of the world The whole programme as thus assembled at Broadcasting House was radiated through all the B.B C. transmitting stations, including three Empire short-wave stations, while various relays were made over the local networks in different portions of the Empire. This broadcast provided simultaneously a tribute both to the very high standard of modern communication technique, and to the excellence of the organisation and international co-operation which are so necessary for its success.

Radio-telephone Link from Scotland to Ireland

THE experiments of the Post Office engineers with ultra-short wave radio-telephony links across the Bristol Channel have already been mentioned in these columns. During December, transmitting and receiving stations were installed in Scotland and Ireland with the view of providing in the New Year six radio telephone channels in the wave-length range 4-5 metres. The *Times* reports that shortly before Christmas, however, the ordinary submarine telephone cables broke down, and three of the new radio links were brought into operation by the postal authorities in order to maintain the telephone traffic between the two countries. The positions of the wireless stations are at Enoch Hill, near Portpatrick, on the Scottish side, and Ballywater, near Belfast, on the Irish side. The sites were specially chosen on account of their height and freedom from obstruction, and at both places there are ample facilities for extension. This wireless link has already dealt successfully with a number of telephone calls from all parts of Great Britain to Ireland, and the callers have, without knowing it, been taking part in an important experiment in wireless telephony. An antenna array is used at each station to concentrate the radiation into a beam in the desired direction, and the telephone communication may thus be regarded as secret for most practical purposes. The development is of particular interest to Scotland, because of the possibility of applying the system to link up many districts in the Western Isles that are at present isolated so far as telephone communication is concerned. The laying of submarine cables is very expensive, and it is likely that the radio link will provide the means of linking up many districts on the west coast at very much lower cost.

A Radio Beacon at Southampton

THE coasts of the British Isles are already equipped with a number of fixed radio beacons, which frequently and automatically emit characteristic signals for the use of ships fitted with radio direction-finders. Such beacons are found to be of great assistance to marine navigation, particularly during foggy or stormy weather. According to the Southampton correspondent of the *Times*, an agreement has now been reached between Trinity House, the Cunard White Star line and the Southampton Harbour Board, as a result of which a radio beacon will be installed on the Nab Tower for the benefit of ships using Southampton Harbour. This tripartite agreement provides for the sharing of the cost of installation and maintenance of the beacon, which, however, will be owned and operated by Trinity House, the authority to which all similar fixed beacons in Great Britain belong. The decision to carry out this new installation is particularly opportune, as the Compagnie Générale Transatlantique has just decided that, in future, all its westbound steamers from France to America will call at Southampton.

British Empire Air Mails

SIR PHILIP SASSOON, speaking in the House of Commons recently, outlined fresh proposals for the development of Empire air communications. These, he stated, represent His Majesty's Government's considered scheme, but are necessarily provisional until the other Empire Governments concerned have examined them. There are three main features: an improvement on present time schedules, an increase of frequency of service, and the automatic transfer of all first-class mail to air transport. The new proposals envisage a time of seven days to Australia and four days to the Cape, with proportionate times for intermediate places. This will be made possible by progressive development of ground organisation to enable night flying to operate over the whole of the routes. There will be possibly five services a week to India, three to Singapore and East Africa, and two to Australia and South Africa respectively. It is hoped to keep the charge the same as the present Empire rate of 1½*d* by reducing the permissible weight to half an ounce. It is suggested that correspondence covering eight sides of a special light paper can be sent within that limit. The new services will cater for passengers as well as mail. The completion of the negotiations, provision of the necessary fleet, ground organisation, etc., will take at least two years, and the Postmaster-General has stated that there is little possibility of the introduction of the new postal rate before 1937.

150th Anniversary of *The Times*

ON January 1, 1785, *The Daily Universal Register* began publication as a modest news sheet at the price of 2½*d*. The journal was intended, in the first place, as much to advertise the Logographic Press, set up by John Walter near Printing House Court or Yard, Blackfriars, as to function as a newspaper. The title of the paper soon became *The Times*, which now celebrates its one hundred and fiftieth anniversary by the publication of a supplement of thirty pages, in which the history and activities of the paper are surveyed. During the past century and a half, both the technique of printing and the art of news gathering and presentation have been revolutionised, largely through the progress of scientific developments. *The Times* was printed at first on hand-presses, which turned out about 250 copies an hour. On November 29, 1814, the steam printing machine developed by Friedrich Koenig (1774–1833), was used, which immediately increased the output to more than a thousand copies an hour. Since then progress has been rapid and speeds of 40,000 copies an hour are now in use. On the side of news gathering, progress has been even more spectacular. In the early days, foreign news came mostly from foreign journals. Nowadays, all the channels for rapid communication opened up by science are utilised to the utmost. Correspondents are appointed in the principal cities throughout the world or sent specially to places of interest, from which the latest news and reports are transmitted, by telegraph and radio, in word and

picture By demonstrating the practical utility of modern methods of rapid conveyance of news and equally by recording scientific developments wherever they occur, *The Times* has played a noteworthy part in the rapid progress of the past century

Rural Conditions in Roman Britain

A NOTABLE addition to our knowledge of the conditions of farm life in Roman Britain is made by the account of an excavation of farm buildings in Carnarvonshire carried out by Mr B H St J O'Neil on behalf of the Office of Works, which is described in the *Times* of December 29 The site is on Caerau farm, north of Pant Glas station, in an area which has already afforded evidence of similar cultivation sites, evidently parts of a rural group or community centring on the Roman fort of Segontium, at Carnarvon, and in which the ancient field system of terrace cultivation can still be readily discerned Of a succession of four ancient farms along the hill-side, facing the west, one is practically intact Within what is described as an excellent system of ancient fields, rising one above another, are two separate courtyard houses, of which the first is an oval about 100 ft long, bounded by a stone-faced wall of earth or turf It was approached by a cobbled road 8 ft wide, which passed through an opening in the wall into the courtyard On this yard two rooms now open, but originally there were four These rooms are circular, the larger having a diameter of 25 ft Their structure is interesting The walls are now 4 ft high and may never have been higher The roof was supported by six posts, for which the holes remain, mid-way between the wall and the centre of the building, where there may also have been a post The room was provided with a stone bench on the west side, drains and a trench which may have been a slot to receive a wooden partition, dividing the room into two The smaller hut, which also had a system of drains and gulleys, apparently was used for industrial purposes, the find of a crucible and two hearths suggests the reduction of metals The second house on the edge of the field system has a polygonal boundary wall with a well-defined entrance and at least five rooms around the courtyard One room appears to have had a ridge roof The numerous pottery fragments are typical Romano-British of the second and third centuries A D

The Vertebrate Evolutionary Tree

FOR long we have accepted as well-established and equivalent the five classes of vertebrate animals, but recent zoological research, particularly on the palæontological side, has modified many old conceptions of relationship and suggests that there may be need for readjustment in the major groups An attempt at a new classification which will give due weight to recent discoveries has been made by G. Säve-Söderbergh (*Arkiv. zoologi*, 26, No 17, 1934). Its main suggestions are that the present class Pisces is a medley of two of the three main stocks of Gnathostomes and parts of a third one. This third stock (Choanata) gave rise to the higher vertebrates, but probably by two routes, the ancestors of the Dipnoi leading to the Urodela, of the Crossopterygii to the Anura by a devious route. The Amphibia also must be looked upon as a mixed assemblage, which includes the two stocks just mentioned, but also an offshoot of the reptilian Reptiliomorpha, the Anthracosauria. Finally, birds and mammals belong to a richly branching part of the vertebrate phylogenetic tree, most of the branches being grouped as reptiles, while two equivalent branches are given unequal status as the independent classes Aves and Mammalia The author regards it as absurd that equal systematic value should be given to these classes as to the fundamental group Pisces composed of two entire stocks of Gnathostome vertebrates, and half of the third stock The writer's first reaction to this interesting and revolutionary view of vertebrate phylogeny, in which birds and mammals are grouped with reptiles and Anthracosauria as equal divisions of the Reptiliomorpha, is the thought that systematic classification is not entirely a matter of equivalents, and that even when phylogeny is known, weight must be given to outstanding novelties in evolution which have originated decisive lines of development Thus the 'invention' of warm-bloodedness, which by adding to the adaptability of vertebrates has enabled them to conquer land surfaces far beyond the reptilian range, seems worthy, in association with the structures which made it possible, of a distinctive classificatory label

Starlings in London

FOR some years, enormous numbers of starlings have taken to roosting on the ledges of buildings in central London, where they spend the winter nights in safety on such buildings as the National Gallery, Somerset House, St Paul's and Covent Garden In Edinburgh, similar hordes frequent the roof ledges of the General Post Office and other buildings in the neighbourhood The winter population of starlings in large towns must be unbelievably large, yet it appears still to be increasing In the report for 1933 of the Committee on Bird Sanctuaries in Royal Parks (England), C S. Bayne states that in 1933 (for the first time) starlings roosted on Duck Island in St James's Park without an interval In the first week of May, when winter roosts are usually deserted, he counted there eight thousand of them, but the numbers were greatest in autumn before the usual contingents moved in November to take up their winter quarters in Trafalgar Square It is a matter of some interest to know whence come the starlings that flock to London at night, and R. W. Hale has discovered one of the sources He has watched the birds feeding on and near Hendon Sewage Farm, and has seen them leave there in flocks about two hours before sunset. The flight of the flocks he has tapped at Cricklewood Lane, Finchley Road Station, Lord's and Baker Street Station. A line drawn through these points and extended passes through Trafalgar Square, so the slightest deviation from this would bring them over St. James's Park, and some of the largest flocks which settle in St. James's Park come from that quarter.

No 3401 JANUARY 5, 1935

Heavy Water in Chemistry*

By PROF M POLANYI, University of Manchester

CONFLICTING DEFINITIONS OF ISOTOPY

ONE gram is the weight of one cubic centimetre of water at 4° C One cubic centimetre of heavy water weighs about 10 per cent more, that is, 1 1 grams. The molecule of heavy water is composed of hydrogen and oxygen, in the same proportion as that of ordinary water , two hydrogen atoms being united with one oxygen atom Nor is there anything unusual about the oxygen atom in this heavy water molecule But the hydrogen is different from ordinary hydrogen Its atomic weight is 2 instead of 1, and to this new sort of hydrogen all the heaviness of heavy water is due

It is this heavy hydrogen, discovered by Prof H C. Urey in New York, which interests chemists in heavy water At first sight, this interest may well seem unjustified Heavy hydrogen is not a representative of a new class of substances It is to be considered as an isotope of hydrogen, which is accompanied by it in the same way as almost every element is accompanied by one or more of its isotopes Lead, for example, which is mainly constituted of atoms weighing 208 units, contains in addition atoms of weights 203, 204, 205, 206, 207, 209 and 210 In chlorine there is, beside the main part consisting of atoms of weight 35, another kind of atom weighing 37 which forms as much as one third of the element

The discovery by Soddy, more than twenty years ago, of the existence of isotopes, and the disclosure by Aston, with his mass-spectrograph, of the isotopic composition of the elements, were great discoveries But in the years that have followed, new isotopes have ceased to arouse general interest, and even when, more recently, the three basic elements of organic chemistry and of living matter, carbon, oxygen and nitrogen, were found to contain a fair amount of heavier isotopes, namely, a carbon of weight 13 beside that of weight 12, nitrogen of weight 15 beside that of weight 14, oxygen of weight 18 beside that of weight 16, these discoveries did not arouse much interest among chemists Indeed, many excellent chemists of my acquaintance have taken no notice of these new isotopes

Why, then, is the new isotope of hydrogen viewed so differently from other isotopes that some chemists consider its discovery to be possibly the greatest advance in chemistry made in this century ? The answer is, because it does not behave as an isotope at all So much so, that Prof Soddy, the discoverer of isotopy, has, in contradiction to the general view, actually repudiated its claim to be regarded as a true isotope Prof Soddy upholds the original definition of isotopy, according to which two elements should be called isotopes if they cannot be separated from one another by any chemical means By this standard, the two different hydrogens should certainly not be considered as isotopes Heavy hydrogen is easily separable from ordinary hydrogen. Water containing 95 per cent of heavy water is available, not as a natural product, but manufactured, by Imperial Chemical Industries Ltd in England, from ordinary water which contains only 1/4,000 of heavy water. Evidently, a very effective separation of the heavy hydrogen from the ordinary one has been carried out in this case. Also there is no doubt that the process used for the separation is a chemical one

The preparation consists in a process of electrolysis The first indications of the separability of the two hydrogens by electrolysis was discovered by the late Dr. E. W Washburn and Prof Urey, who found that when water is decomposed by electrolysis, the undecomposed residue has a somewhat greater density than ordinary water. The purification of heavy water on this basis is due to Prof.

* Friday evening discourse at the Royal Institution, delivered on November 23

G N Lewis of California, who has shown that by decomposing very large quantities of water until only a small residue remains, almost pure heavy water is obtained

There is plenty of other evidence for chemical differences between ordinary and heavy water Generally, the compounds of heavy hydrogen react more slowly than the corresponding ordinary hydrogen compounds The greatest difference has been described by Prof Urey in the reaction between water and aluminium carbide, which leads to the formation of methane Heavy water reacts twenty times more slowly than ordinary water

Why, then, if the two hydrogens are so different, do chemists generally agree to consider them as isotopes ? The answer is, because the two hydrogens, although chemically different, are true isotopes with regard to the structure of their atoms

The amplification of the original definition of isotopes implied in this opinion is the natural outcome of the theory of Rutherford and Bohr on atomic structure We can illustrate this structural

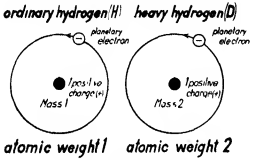

Fig 1 The isotopes of hydrogen

view of isotopy by comparing the atomic models of the two sorts of hydrogen atoms These are shown in Fig 1 according to Bohr's theory The two atoms are equal in every respect, apart from the difference in the masses of their nuclei Two atoms thus related to one another are considered to be isotopes from the structural point of view

Until the discovery of heavy hydrogen, atoms which have the same structure, and differ from one another only in the mass of the nucleus, have always been found to possess identical chemical properties.

It is easy enough to show reasons why this should be so. The forces originating from an atom are due to the electric field of the charges contained in it. Two atoms with identical electric charges, identically distributed in space, will therefore originate identical forces. It is therefore to be expected that such a pair of atoms should have equal chemical properties

The astonishing thing is that this should not hold for the two sorts of hydrogen atoms, that these two, although giving rise to identical forces, should have different chemical properties. How can the mere difference in nuclear mass cause such marked chemical differences as shown by the two hydrogens ? If mass differences can cause such disparities, why have they never become apparent in other known pairs of isotopes—why has this mass effect remained undisclosed up to the discovery of heavy hydrogen ?

Only when we can answer these questions fully, shall we be quite justified in considering heavy hydrogen as an isotope of ordinary hydrogen.

Now there is a certain difference in chemical properties caused by mass differences, well known for a long time, which we must expect to find more accentuated between the two sorts of hydrogen atoms than between any other pair of isotopes known hitherto This difference has its origin in the motion in which all particles around us are kept by the *heat* contained in matter The thermal velocity of a lighter particle is greater than that of a heavier one A particle moving faster will reach a molecule with which it might react faster than its slower competitor, it will therefore be found to react more quickly, just as light hydrogen reacts more quickly than heavy hydrogen

The chemical differences which arise from thermal velocities will depend on the *ratio* of the atomic masses. This ratio is certainly more marked in the case of the two hydrogens than in any other element It is 1 : 2 for the hydrogens, while in the element coming next to these, namely, the pair of lithium atoms of mass 6 and 7, there is a ratio of only 1 : 1·2. There is thus a good *prima facie* case for attributing the chemical differences between the hydrogen isotopes to their different thermal velocities

However, this explanation, although it looks so promising at first sight, turns out on closer examination to be an incorrect one. First, calculation shows that the differences in thermal velocities are quite insufficient to account for the differences which have been actually found between the reaction velocities of the two hydrogen isotopes. Secondly, there are some dissimilarities to be described presently between the compounds of the two hydrogens, which prove that these compounds differ in their *energy content*. Consideration

of thermal velocities cannot account for such energy differences

We must, therefore, postulate a cause apart from the differences in thermal velocities, for the explanation of the actual dissimilarities of the two sorts of hydrogen We shall see that this cause is to be found by applying to our problem one of the more recently discovered principles of Nature, namely, the uncertainty relation of Heisenberg

The Law of Uncertainty

The uncertainty principle states that no information can be obtained about the velocity of a particle the position of which is known with absolute accuracy *Certain* information about the velocity can be arrived at, if we admit a *certain inaccuracy* of position Thus, the two inaccuracies remain tragically linked together in the formula

$$\text{Inaccuracy of position} \times \text{inaccuracy of velocity} = \text{constant}$$

Our information on position and velocity has in it a compound inaccuracy which is irreducible

From this uncertainty, however, we can derive a dynamical principle latent in all matter, which acts against a force holding a particle, and in doing so modifies the effects of the force It will also appear that the effect of this dynamical principle depends on the mass of the particle, and is, therefore, different for two atoms giving rise to identical forces, but differing in mass We shall then see that this is the true reason why the two hydrogen atoms are so different

A fictitious experiment will enable us to recognise the dynamical principle in question Suppose we attempt to defeat the uncertainty principle by sheer force. We take an atom and hold it at rest in some fixed position. If we succeed in doing this, we would obviously overthrow the law of uncertainty. The position of our atom would be exactly known and, since we suppose it to be held at rest, its velocity would also be known to be exactly equal to zero.

The law of uncertainty predicts that our experiment will fail Any force trying to keep an atom in a fixed position would be defeated by a power given to the particle to defend its uncertainty It will defend it by starting to vibrate. The tighter we try to hold the atom to stop this vibration, the more violent would the vibration become. No force would be strong enough to keep the particle in place, motionless.

The uncertainty law thus leads to the following postulate · Any particle restricted to a definite range of positions is necessarily in motion , the range of velocities contained in this motion will be the wider, the narrower the restriction of positions , that is

$$\text{Range of positions} \times \text{range of velocities} = \text{constant}$$

In Nature, atoms are restricted in their position when linked up to chemical compounds Such restrictions, we must conclude, will give rise to an uncertainty motion of the atoms All molecules will hence contain a certain amount of uncertainty motion, and also, since this motion has kinetic energy attached to it, a certain amount of corresponding energy We might also postulate that the more restricted the positions of the atoms in the molecule are, that is, the stronger the bonds that hold the atoms in position, the more violent will be the uncertainty motion, and hence the greater will be the energy content of the molecule, due to uncertainty

Next to bond strength, atomic mass will influence the uncertainty motion This influence of mass is contained in the constant of the uncertainty formula, which can be written

$$\text{Range of positions} \times \text{range of velocities} = \frac{\text{universal constant}}{\text{mass}}$$

Thus the composite uncertainty on the left hand side of the equation is smaller the larger the mass of the particle Hydrogen of mass 1 will have a compound uncertainty twice as large as hydrogen of mass 2 Under equal conditions, therefore, the uncertainty motion and the energy of this motion will be larger for light hydrogen than for heavy hydrogen , in corresponding molecules containing the two sorts of hydrogen, there will be more 'uncertainty energy' present when the molecule contains ordinary hydrogen than when it contains the heavy isotope

Compare, for example, ordinary water with heavy water For ordinary water, the 'uncertainty energy' amounts to 13,097 cal , for heavy water it is only 9,527 cal Since the uncertainty energy is only present in molecules, and vanishes when the atoms are set free, it follows that less work is needed to break up an ordinary water molecule into free atoms than to separate the atoms of heavy water This is illustrated graphically by Fig. 2. From such differences in the energy contents of the corresponding molecules, all the differences in the chemical properties of the two

hydrogens arise I will show this in the remaining part of my lecture, but before turning to this, I wish to emphasise two points First, that the attribution of the exceptional dissimilarity of the two hydrogen isotopes to the exceptionally high ratio of their masses is not correct Suppose a lead isotope should be discovered having double the mass of ordinary lead Such an isotope would be chemically indistinguishable from ordinary lead, because the 'uncertainty' attached to a particle of the mass of a lead atom is imperceptible, and hence no variation of this uncertainty can be detected Secondly, the permanent character of the atomic motion, which is required to keep up the uncertainty of velocities, should be clearly realised Atoms and molecules are ordinarily kept in, what may seem to us, perpetual motion by heat But heat can be passed on to a cooler body, or be lost altogether by radiation In the distant future, all heat may become lost by radiation, and all thermal motion may die out But beyond

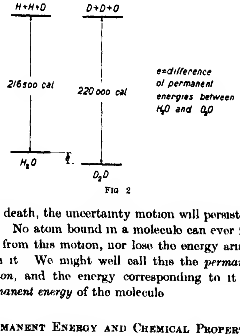

FIG 2

that death, the uncertainty motion will persist for ever No atom bound in a molecule can ever find rest from this motion, nor lose the energy arising from it We might well call this the *permanent motion*, and the energy corresponding to it the *permanent energy* of the molecule

Permanent Energy and Chemical Properties of the Hydrogen Isotopes

We have now to show in what way the differences in permanent energies cause the dissimilarities in the properties of the ordinary and the heavy hydrogen.

The curves in Fig 3 show the permanent energies of both the ordinary and the heavy hydrogen halides Since the bond strength of the hydrogen halide molecules decreases in the sequence → Cl → Br → I, we might expect—remembering that the permanent energy is greater the tighter the bond which holds the atoms in position—that the permanent energy will decrease in the sequence of falling bond strength. This is well borne out by both curves, which show consistently a decrease in the sequence HF → HCl → HBr → HI, and likewise in the corresponding sequence DF → DCl → DBr → DI

The reduction of permanent energy which has been deduced from the uncertainty principle for the case of H being replaced by D is also clearly shown The D-curve lies everywhere below the H-curve The relative depression of the permanent energy is very nearly equal for all four compounds Consequently, the absolute value of the difference in permanent energies is the greater the higher the permanent energy of the original compound This relation when connected with the above-

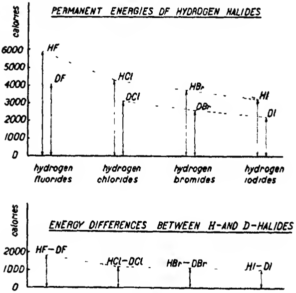

FIG 3

mentioned rule governing the sequence of the permanent energies leads to the important conclusion, illustrated by the lower part of Fig. 3, that the differences in the permanent energies of corresponding H and D compounds fall off in the sequence of decreasing bond strength. Or, putting it in a more general way the contrast between two corresponding ordinary and heavy hydrogen compounds will differ from compound to compound and will be the more marked the firmer the bond by which the hydrogen is linked in the compound

The energies in Fig. 3 are not measured data, but values calculated from molecular theory. A little further discussion leads us to a very sensitive

method of checking these theoretical results The diagram shows us that if we replace H by D in hydrogen fluoride, the energy will fall by about 1,600 cal, that is, this amount of energy will be gained Similarly, if we replace H by D in hydrogen iodide, we gain about 900 cal We can express this in the following chemical equations

$$D + HF = DF + H + 1{,}600 \text{ cal} \quad (1)$$
$$D + HI = DI + H + 900 \text{ cal} \quad (2)$$

By subtracting equation (2) from equation (1) we obtain, after a slight rearrangement

$$HF + DI = HI + DF + 700 \text{ cal}$$

Hence an interchange of H and D between HF and DI is a reaction in which energy is set free Since reactions always tend to go in the direction in which they produce energy, we might expect that in a mixture of hydrogen fluoride and hydrogen iodide which have between them a certain amount of heavy hydrogen, the heavy hydrogen will have the tendency to unite with fluorine rather than with iodine

An experiment to test this conclusion could be carried out in the following way A quantity of heavy hydrogen could be prepared by decomposing heavy water, for example, by electrolysis We might use one gram of water, containing 1 per cent of pure heavy water, and by completely decomposing it, produce about one litre of hydrogen containing 1 per cent heavy hydrogen From one half of this we could make, with fluorine, one litre of hydrogen fluoride containing 1 per cent of DF The other half would go to form 1 litre of hydrogen iodide containing 1 per cent DI We could now let the two gases mix together in a two litre vessel, and add a trace of water to catalyse the interchange of hydrogen atoms between the two gases On separating the gases and estimating how much heavy hydrogen is contained in each of them, we should find that heavy hydrogen accumulates in the hydrogen fluoride, which will contain about 1 3 per cent of D as against 0 7 per cent of D in the hydrogen iodide.

By carrying out the experiment at a low temperature, for example, − 150° (supposing that an efficient catalyst could be found), the distribution of D would become even more unequal, namely, 1 8 per cent D in hydrogen fluoride as against 0·2 per cent D in the hydrogen iodide

Interchange Reactions of Hydrogen Atoms

Such interchanges of H and D between two hydrogen compounds have been the object of numerous studies, especially at the Universities of Manchester and Cambridge, in Manchester the work was mainly done by Dr J Horiuti, the work in Cambridge is due to Dr A Farkas, Dr L Farkas and Prof E K Rideal Indeed, the principal part played by heavy hydrogen in chemistry is in some way or another connected with such interchange processes

Suppose that we bring together the two gases, hydrogen and hydrogen iodide, and add to these the three liquids, water, benzene and ethyl alcohol, and suppose also that we have appropriate catalysts present to bring about the interchange of the hydrogen atoms between all these compounds, then, after separating the substances, we shall find that each contains a certain part of the heavy hydrogen present in the mixture This characteristic quota of each compound will specify the relative preference which it gives to D over H

Distribution of D between different hydrogen compounds

Hydrogen compound*	Specific quota	Reference
HI	0 17	Calculated from known equilibria
H_2	0 33	A Farkas and L Farkas (*Trans. Far Soc*, **30**, 1071, 1934)
H_2O	1 00	(Arbitrary unit)
C_6H_6	0 95	J Horiuti and M Polanyi (NATURE, **134**, 377, 1934)
C_2H_5OH (hydroxyl group only)	1 5	C E H. Bawn (unpublished)

* The symbol H used here includes both kinds of hydrogen

A list of these quota figures for the five compounds mentioned above is given in the accompanying table, in which the units are, of course, arbitrary From what has been said above, we know that these figures depend on the differences of permanent energy between the ordinary and the heavy compounds We obtain from these figures a rather intimate knowledge about the permanent energy of different compounds which otherwise would not be easily accessible to measurement

The capacity of some substances to accumulate a comparatively high quota of the heavy hydrogen present in a mixture can be utilised in the following way. Suppose we bring hydrogen iodide containing some D into contact with alcohol, then we shall find on separating the two substances a

concentration of heavy hydrogen about ten times greater in the alcohol than in the hydrogen iodide If we carry out the process at low temperatures, for example, at $-80°$ C, the ratio of the two concentrations will be as high as 30 to 1

Processes of this kind may promise to be of use for the manufacture of heavy hydrogen Ordinary hydrogen contains, as I have said, about 1/4,000 of heavy hydrogen To concentrate it from this dilution at a reasonable cost is as yet an unsolved problem

Suppose we convert the hydrogen gained by decomposing ordinary water into hydrogen iodide, and then pass this hydrogen iodide through alcohol at $-80°$ C, we should get an alcohol containing almost 1 per cent of heavy hydrogen in its hydroxylic hydrogen By decomposing the hydroxyl group of the alcohol, for example, by metallic sodium, a hydrogen containing almost 1 per cent of heavy hydrogen would be set free, and it would be easy to arrive at highly concentrated heavy hydrogen by repeating the process once or twice In practice, this process would probably fail on account of the unavoidable losses of iodine and of alcohol, which would make it fairly expensive

Similar processes based on the unequal distribution of heavy hydrogen between different substances will probably be found practicable sooner or later, and might then bring down the price of heavy hydrogen to the point where it could be used in the manufacture of the more valuable chemical products, such as drugs and dyestuffs.

Another interest attached to the interchange of hydrogen atoms between different hydrogen compounds lies in the possibility which they offer for the preparation of the more complicated compounds of heavy hydrogen It is, of course, not impossible to build up all sorts of heavy hydrogen compounds by synthesising them from their elements, using heavy hydrogen instead of ordinary hydrogen But this procedure might prove rather awkward with many very common substances usually not prepared by synthetic processes, such as benzene, naphthalene, anthracene However, it seems easy to prepare the heavy hydrogen compounds corresponding to benzene, naphthalene, etc, by taking the ordinary substances and replacing in them the H atoms by D atoms.

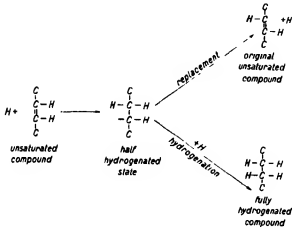
Suppose we want to make benzene with the hydrogen atoms substituted by heavy hydrogen atoms, that is, C_6D_6. A synthesis could be carried out by polymerising synthetic heavy acetylene It seems much simpler to bring the benzene into contact with pure heavy water, adding an appropriate catalyst to let the two substances exchange their hydrogen atoms. If we take 10 gm of heavy water and 1 gm of benzene, about 90 per cent of the hydrogen in the benzene should be replaced in one process A repetition of this procedure should give us benzene containing 99 per cent D in its hydrogen This process is now being tested in Manchester.

The interchange of hydrogen atoms of different compounds has also an interest as a new type of chemical reaction, often related in an interesting way to other 'true' chemical reactions Consider, for example, the replacement of ordinary by heavy hydrogen in benzene The quickest way to obtain this replacement is by bringing heavy hydrogen into contact with benzene at room temperature in the presence of a nickel or a platinum catalyst These catalysts are well known for their capacity to cause the addition of hydrogen to unsaturated compounds, in their presence, ethylene, for example, will react very rapidly with hydrogen to form ethane Benzene likewise adds on hydrogen, forming hydro-benzene, but much more slowly. The replacement reaction will, therefore, be accompanied by a hydrogenation of benzene But experience has shown that the hydrogenation is very much slower than the replacement Only one in a hundred molecules, reacting in the sense of replacement, reacts also in the sense of hydrogenation.

The replacement of ordinary by heavy hydrogen in benzene can also be carried out by bringing heavy water into contact with benzene. This reaction proceeds also in the presence of platinum and nickel catalysts, but it goes much slower than the interchange between ordinary hydrogen and benzene Higher temperatures and longer times are required when heavy water is used for replacement; there is, of course, no hydrogenation whatever

We note that both the hydrogenation and the replacement of hydrogen atoms represent a transfer of hydrogen atoms to the benzene The two processes differ only in the result obtained by the transfer of the hydrogen atom, while in the case of *hydrogenation* the transfer results in the formation of hydrogenated products, like ethane from ethylene, or hydrobenzene from benzene, *replacement* proceeds without any accompanying chemical change.

These alternative reactions can be shown by the following reaction scheme



A hydrogen atom meeting an unsaturated molecule first forms a half-hydrogenated product This substance then, if left to itself, decomposes by dropping one of its redundant hydrogen atoms (see upper arrow), whereby there is at least an even chance that the hydrogen atom lost is not the same one as had been added, and that, in consequence, the result is the replacement of a hydrogen atom This decomposition of the half-hydrogenated state can, however, be forestalled if a second hydrogen atom comes up before it is accomplished (see lower arrow), and links up to the half-hydrogenated molecule, forming a fully hydrogenated compound

If this explanation is correct, hydrogenation will be rare when the interval between the approach of the first and second hydrogen atom is long. In such cases, the reaction will result almost exclusively in replacement of hydrogen atoms, unaccompanied by hydrogenation.

This conclusion is well borne out by our experiments, which show that while a more energetic action of hydrogen on benzene (when gaseous hydrogen is brought into contact with it) causes a replacement of hydrogen atoms, which is accompanied by a quite appreciable amount of hydrogenation, no hydrogenation is found when the action of hydrogen is slow, as, for example, when water is the source of the hydrogen atoms reacting with benzene. Thus the replacement reaction discovered by the use of heavy hydrogen discloses the nature of hydrogenation, which appears now to be a side reaction of the replacement reaction. Similar success may be expected in many other cases.

Low Reactivity of Heavy Hydrogen Compounds

The study of the hydrogen interchanges, to which we originally turned in order to derive information on the energy differences between the ordinary and the heavy hydrogen compounds, has led us away from our starting point We return now to the question raised at the beginning of this lecture—the lower reactivity of heavy water as compared with ordinary water

It is as yet uncertain to what extent the lower reactivity of heavy hydrogen compounds can be considered to be a general rule But it is certainly a fairly widespread condition The possible interest of such lower reactivity is, of course, manifold Hydrogen compounds which ordinarily are readily oxidised or otherwise decomposed might become stable if the ordinary hydrogen is replaced by heavy hydrogen Reactions might be led into new paths or else their output might change considerably Theory and practice would profit abundantly by such phenomena

This lower reactivity of heavy hydrogen and of the compounds of heavy hydrogen can be explained by the theory of permanent energy with which I have already dealt Indeed, it was predicted from this theory when there was still scarcely any experimental evidence for it

The essential connexion between permanent energy and reactivity is easily recognised A molecule undergoes chemical reaction only if it happens to accumulate a certain critical amount of energy The molecule has to wait until, in the course of the constant fluctuation of energy caused by heat motion, it happens to get an especially big share of energy equal to this critical energy As soon as it has swallowed this, it goes to pieces —that is, chemical reaction

Now suppose we have two molecules, one a compound of ordinary hydrogen, the other, the corresponding compound of heavy hydrogen Let both molecules wait side by side until, by a fortunate fluctuation of thermal motion, they acquire the critical energy necessary for reaction The ordinary hydrogen molecule is obviously in a better position in this competition, since it has a start on account of its greater permanent energy. The energy required by it is correspondingly smaller, and it will have an earlier chance to get this smaller quantity It will, therefore, react before its competitor, the heavy hydrogen

compound This is the reason for the lower reactivity of heavy water, and of other heavy hydrogen compounds

Water with Heavy Oxygen

I have mentioned before that ordinary oxygen of atomic weight 16 is accompanied by small quantities of a heavier isotope of weight 18 This heavy oxygen forms with hydrogen a heavy water of a kind quite different from 'ordinary' heavy water H_2O^{18} in pure form would have about the same density as D_2O, that is, 10 per cent above that of ordinary water The two sorts of heaviness could be combined in 'super-heavy' water, D_2O^{18}, which would have a density of 1 2

It is, however, much more difficult to prepare pure heavy oxygen than it is to prepare pure heavy hydrogen Although the abundance of heavy oxygen in ordinary water is eight times higher than that of heavy hydrogen, it has not yet been isolated The difficulty is that the two sorts of oxygens are chemically identical, and hence we have no convenient hold whereby to grasp the one, leaving the other behind The separation can be carried out only by physical methods which are comparatively ineffective

The best physical method for the separation of isotopes is at present the 'fractionated diffusion' of G Hertz By this method, Prof Hertz has succeeded in preparing about 300 mgm of water containing about 1 mgm of heavy oxygen Prof Hertz gave us this sample and Dr Szabo and the author have made the following use of it

To the water we added a small quantity of metallic sodium, thus forming an alkaline solution Then a few milligrams of amyl acetate were treated with this solution until completely saponified From the amyl alcohol produced by the saponification, the hydroxyl group was split off in the form of water We examined this water, and found that *its density was normal*

It follows that this oxygen does not come from the water used for saponification . it must, therefore, come from the oxygen of the ester-bridge. Or, in chemical symbols

$$\text{AmO Ac} + H_2O^{18} = \text{AmOH} + \text{HO}^{18}\text{Ac}$$

and *not*

$$\text{Am OAc} + H_2O^{18} = \text{AmO}^{18}\text{H} + \text{HOAc}$$

This decides a question that had remained open since it was first raised by Van t'Hoff in 1899 Although the answer may only confirm what many chemists had surmised before, still it shows how useful heavy oxygen might become for the elucidation of the mechanism of oxygen reactions such as hydrolysis, oxidation, etc

Heavy Isotopes of other Important Elements

We have seen that the differences in the chemical properties of ordinary and heavy hydrogen are interesting, both in themselves and as a means of preparing pure heavy hydrogen But often the heaviness of the new hydrogen is used merely as a convenient 'label' to mark the path which the hydrogen follows, when it becomes mixed and interchanged with other hydrogen atoms For this labelling purpose, the heaviness of heavy oxygen, O^{18}, has turned out to be just as useful a tool where reactions of oxygen are concerned The same is obviously true for N^{15} and C^{13}, with respect to the study of reactions involving nitrogen and carbon*

Heavy hydrogen has a start over the other isotopes of the more important elements, because it was the first to be isolated in quantity When we have the other isotopes at hand in sufficient quantities, they may well prove even more important than heavy hydrogen All branches of chemistry will benefit by such progress, but it is likely that the greatest stimulus of all will be given to the chemistry of living matter when such labelled carbon, hydrogen, oxygen and nitrogen atoms will become generally available

* Labelling of atoms by isotopes was first introduced by Hevesy and Paneth in their method of 'radioactive indicators' (See, for example, Hevesy and Paneth, "Lehrbuch der Radioaktivität" J A Barth, Leipzig (1923), p 105)

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO LTD., ST. ALBANS

Forestry in British Honduras

THE chief note of the annual report of the Forest Trust of British Honduras for the biennial period ending March 31, 1933 (Govt Printer, 1934) is one of marking time The Department has now had ten years experience, but the increasing depression in the trade of the Colony necessitated economy during the period under review and the personnel was reduced to a skeleton service The Forest Trust had early decided that further sylvicultural work, with its long lock-up of capital, was to be discontinued, and all reserves were placed on a 'care and maintenance' basis, an expression which will convey little to the forester possessing an acquaintance with the tropical forest The energies of the Department are to be applied, therefore, to the furtherance of research work into the exploitation and marketing of the secondary timbers, with the view of taking prompt advantage of the recovery of world trade, when the present depression lifts So far as it goes, this may be regarded as satisfactory, but the Department will have a long row to hoe before the position of half a decade or so ago is re attained The following extract from the report in connexion with *taungya* is of importance and should interest West African forest officers "The practice of seeding-up the annual corn-plantation with mahogany continues to give excellent results Mahogany seed is dibbled in lines with the maize at 10 by 10 feet intervals, and the area is abandoned after the first crop has been harvested The mahogany is then sufficiently established to compete with the weed growth, which very quickly closes the canopy Over-topping of the mahogany by weed-growth is found to be beneficial in preventing shoot-borer (*Hypsiphylla grandella*) attack. Tending consists of removing vines It is becoming very apparent that huamil (secondary growth) conditions are very favourable to the growth of mahogany, which grows well whilst its head is just under huamil canopy, and that heavy cleaning is not only undesirable but often disadvantageous in rendering the mahogany susceptible to the shoot-borer attack"

Preservation of Newspaper Records

NEWSPAPERS are an important class of historical records as they give a clear view of contemporary life and events The newspaper files preserved in libraries give valuable reference records for historical purposes Unfortunately, the paper on which they are printed is often made of crude ground wood fibre, which rapidly perishes, and the space they take up in libraries is excessive In publication No. 145 of the U S. Bureau of Standards (Washington 5 cents), B. W. Scribner describes researches that have been made on methods of preserving newspapers For retarding decay, the use of Japanese tissue paper has been found effective Transparent cellulose acetate sheeting is also useful Pending the development of more satisfactory materials and methods, an effort should be made to copy the most valuable of the older newspaper records on permanent paper by photostatic printing or photolithography. Reproduction in miniature is the ideal method of reducing the space required The technique of making miniature prints of newspaper records on transparent slides and projecting them in enlarged form for reading is making satisfactory progress The life of the types of flexible film so far used is only about thirty to forty years It is recommended that a joint effort be made at once by scientific and library organisations to find the most practical means for preserving newspaper records Special stress should be laid on perfecting materials and methods of reproduction in miniature The advisability of founding a central agency for supplying reproductions of newspapers and other records to libraries should also be considered

Rubber and Agriculture

THE rapid development of the rubber industry has been one of the most notable industrial events of the present century Between 1910 and 1933, the net amount of crude rubber exported from the principal producing countries increased from 94,000 tons to 851,000 tons per annum, while the world absorption of the manufactured product rose from 85,000 tons to 814,000 tons during the same period Although the demand for motor tyres has been primarily responsible for this expansion, rubber has now found its place in practically every branch of industry To illustrate the various ways in which it may be used on the farm, the Rubber Growers' Association (2-4 Idol Lane, Eastcheap, E C 3) has issued a booklet entitled "Rubber and Agriculture" In outdoor equipment, not only can tyres of every description be supplied to suit everything from a tractor to a wheelbarrow, but also jointed tracks are successfully made The inconvenience of the ordinary tipping device for unloading lorries is now avoidable by using a vehicle fitted with a rubber movable floor, which discharges on either side as desired In the cow shed and dairy, rubber stalls and flooring, rubber parts to the milking machines and rubber rims to the churns to reduce noise, are some of the uses to which this product can be put In the farm-house itself rubber is becoming increasingly popular; rubber floor coverings, brushes and oven rubber upholstery now being practical propositions, while for the farmer and his family, rubber clothing of various types is a recognised part of their outfit

Small Sparks due to Static Electricity

THE small sparks due to static electricity, similar to those sometimes observed when combing the hair or walking over a thick carpet, have caused fires which cost industry an appreciable amount, both in life and property. According to Science Service, of Washington, D C, a study made by the Fire Protection Association shows that during the last six years 147 fires in the United States have been attributed to this cause A frequent cause of sparking is the friction of an endless belt running over pulleys. In an atmosphere containing a certain amount of inflammable gases, this would be sufficient to cause an explosion which might result in a serious fire.

Static sparks have also been observed when 'dry' liquids like petrol or ether are being handled. When any inflammable liquid is being poured from one vessel into another it should always be discharged so that there is no appreciable fall through the air into the lower vessel It is well known that the human body can store electricity sufficient to cause a small spark when it is brought near an earthed conductor Coal gas can be ignited in this way Cases have been recorded where static discharges from a painter's hand have ignited the vapour from a paint remover In another case, vapours from rubber cement were ignited by a spark from the body of a woman who was working near it

Cæsalpinus and Harvey

IN a letter to the *Lancet* of November 17, dealing with the remarkable absence of any reference in Harvey's writings to his predecessor Cæsalpinus, who is still regarded by some Italians as the discoverer of the circulation of the blood, Dr D F Fraser-Harris remarks that he has recently found the three words "J Cæsalpinus Aretinus" in a translation of the MS notes of Harvey's lectures edited by a committee of the Royal College of Physicians in 1886 He points out, however, that the Christian name of Cæsalpinus of Arezzo was Andreas, so that the initial letter should have been A instead of J He therefore suggests that Harvey, whose handwriting was execrable, really wrote "J Cæs. Arantius", an abbreviation of Julius Cæsar Arantius, the celebrated anatomist of Bologna (1530–89), to whom Harvey afterwards referred in his essay on the placenta when dealing with the relation of the umbilical vein to the uterine vessels In support of this suggestion is the context, in which Harvey is describing the three semi-lunar valves at the base of the aorta and pulmonary artery, on the cusps of which the corpora Arantii are found.

Ramanujan Memorial Prize in Mathematics

IN 1933 the University of Madras offered a Ramanujan Memorial Prize for the best thesis based on original contributions submitted by an Indian (or one domiciled in India) on some definite branch of mathematics, applied or pure The underlying idea was to stimulate interest among the younger mathematicians of India and to attempt in some way to commemorate the spirit of the late S Ramanujan, the first Indian fellow of the Royal Society, whose untimely death in 1920 at the early age of thirty-two years robbed the world of one of the most brilliant mathematicians of his time A number of theses were submitted and the University of Madras has now announced that the prize of value about £70 (nine hundred rupees) has been divided equally between the following S. Chandrasekhar, fellow of Trinity College, Cambridge; S. Chowla, reader in mathematics, Andhra University, Waltair, India; D. D. Kosambi, professor of mathematics, Ferguson College, Poona, India. Ramanujan was the first Indian to be elected to a fellowship at Trinity College, Cambridge, and it is interesting that two of the successful candidates (S Chandrasekhar and S Chowla) are both Trinity men

Air-Conditioning in Mines

WE are informed that air-conditioning plant is about to be installed in the well-known Robinson Deep Mine, Johannesburg, South Africa, the deepest point in the mine being 8,380 ft below the surface of the earth The mine is naturally hot and damp, the high temperature (100°-120° F) being due to adiabatic compression at the lower levels, it is calculated that the temperature increases 5° for an average depth of every 1,000 ft of the mine The air is also very moist, having a relative humidity of 90-100 per cent, owing of course to the necessity of wetting the mine walls after every blast to prevent siliceous dust from being thrown into the air and being inhaled by the workers, thus causing the silicosis which is well known to be the scourge of South African mining It is stated that the air-conditioning, cooling and dehumidifying plant is the largest in the world, and will be capable of dealing with 400,000 c ft. of air per minute It is stated that the cooling effect is equal to 4,000,000 pounds of ice

Research on Silicates

IN *Veröffentlichungen aus dem Kaiser Wilhelm-Institut für Silikatforschung in Berlin-Dahlem* are reprinted a large number of papers published since the beginning of 1932 There are two papers on chemical and thermodynamic aspects of the constitution of glass, two on cements, and one on the specific heats of calcium-aluminium silicates with special reference to the Neumann-Kopp rule Many of the papers are incomplete in the sense that they are part of a series and must be judged as such One paper of particular interest deals with the reactions of glass-forming oxides under high pressures of oxygen, up to 350 atmospheres The authors, H Möttig and W Weyl, consider that in glasses containing lead, plumbates are formed, in glasses containing barium they have evidence of the presence of the peroxide. High oxygen pressure modifies the colouring effect of a given amount of manganese additive

Greenland Researches

THE Oxford University Exploration Club has published in one volume the collected reports from various journals on the work of the Club's expedition to Greenland in 1928 ("Greenland and Spitsbergen Papers" Oxford University Press, 1934). This expedition, under the leadership of Dr. T G Longstaff, aimed at an intensive study of the ecology of a small area in Godthaabs Fjord, and its results have been published in some ten British and foreign journals. These nineteen reprints are now conveniently bound together and include important papers on the vegetation, birds and insects. In addition, the volume embraces four papers, principally geological, on Spitsbergen, the outcome of the Oxford Expeditions to Spitsbergen in 1921, 1923 and 1924. These are supplementary to the collected papers

of those expeditions which appeared previously in the two volumes of "Spitsbergen Papers" The volume shows the extent of valuable work that can be done by a small summer expedition to polar regions, especially when the sphere of work is well defined

Map of Central America and West Indies

A USEFUL map, embodying the latest information, of Mexico, Central America and the West Indies on a scale of 90 miles to an inch is published by the National Geographic Society at Washington It is in the main a political map and relief is shown only by hachures, but a number of spot heights are given Railways and the main highways are shown, and there are many names Insets show the more important West Indian islands on larger scale The colour printing is very clear

Eradication of Prickly Pear in Queensland

THE reclamation in Queensland of land formerly infested with prickly pear (*Opuntia* spp) steadily continues During the year which ended on June 30 1934, 5,300,000 acres were made available for selection or for lease under developmental tenure The total area reclaimed and thrown open for settlement during the past three years is 13,750,000 acres, or approximately 20 per cent of the whole infested region

International Congress of Americanists

THE twenty sixth session of the International Congress of Americanists, which was to have taken place during November in Sevillo, had to be postponed owing to financial and political difficulties in Spain The work of organisation is, however, well advanced and it is hoped that it may still be possible to hold the Congress early in 1935 It is unfortunate that the deliberations of this body, which are invariably of great scientific interest to students of the cultures of aboriginal America, should be subjected to interruption through political unrest It will be remembered that when the Congress last met in La Plata at the close of 1932, conditions were anything but favourable to an international scientific assembly, and, indeed, had it not been for a certain disorganisation arising out of these conditions, it is probable that the invitation of Great Britain would have been accepted and the Congress would have met in London in close association with the First International Congress of Ethnological Sciences in August last

Imperial Botanical Conference

AN Imperial Botanical Conference, commencing on August 28 and lasting two to three days, according to the programme which may finally be arranged, will be held in London this year. The subjects set down for discussion are of general interest to Empire botanists, and include such topics as pasture research within the Empire, the ecology of tropical forests, the application of ecological methods to the study of native agriculture, problems of fruit storage and transport with special reference to tropical conditions, the furtherance of schemes for the closer co-ordination of botanical research within the Empire, etc It is hoped that this Conference will furnish a convenient meeting ground for home and overseas botanists who are on their way to attend the International Botanical Congress which meets at Amsterdam in the week following The chairman of the Organising Committee of the Conference is Sir Arthur Hill, director of the Royal Botanic Gardens, Kew, and the honorary secretary is Prof W Brown, Imperial College of Science and Technology, South Kensington, London, S W 7, from whom further particulars may be obtained

Announcements

MR FRANCIS N RATCLIFFE, assistant in the Natural History Department, University of Aberdeen, has been appointed to the head-quarters staff of the Council of Scientific and Industrial Research, Commonwealth of Australia

THE first volume of the new international botanical yearbook to be known as *Chronica Botanica*, to which reference was made in NATURE of September 29, p 493, will be published shortly Heads of botanical institutions, etc , who have received the questionnaire are therefore requested to return it to the publisher, Fr Verdoorn, P O Box 8, Leyden, Holland, as soon as possible Answers should reach Leyden before January 10 from Europe, January 20 from the United States and Canada, and January 30 from other parts of the world

A RECENTLY issued catalogue of books and periodicals on natural history for sale by Bernard Quaritch, Ltd , covers zoology, geology and palæontology, and contains a good selection comprising more than 2,000 items

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A lecturer in science and hygiene in the Liverpool City Technical School for Women and F L Calder College of Domestic Science—The Director of Education, 14 Sir Thomas Street, Liverpool, 1 (Jan 7) An assistant lecturer in pharmacy in the Technical College, Bradford—The Director of Education, Town Hall, Bradford (Jan 15) Three chemists at the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, S W 7 (Jan 18) Assistant lecturers in metallurgy in the University of Birmingham—The Secretary (Jan 21) Two research bacteriologists in the Medical Research Department of the Government of India—The High Commissioner for India, General Department, India House, Aldwych, W C 2 (Jan 26) A bacteriological research assistant to the Metropolitan Water Board - The Clerk, 173, Rosebery Avenue, E.C 1 (Jan 26) A research assistant in tissue culture and assistant lecturer in histology at the University of Birmingham —The Secretary (Feb. 1) A lecturer in chemistry at University College, University of Rangoon—The Secretary, Universities Bureau of the British Empire, 88A Gower Street, London, W.C 1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 37.

Passage of Helium through apparently Compact Solids

IT has been known for some time that helium can pass at the ordinary temperature through silica glass, and also, to a less extent, through pyrex glass Common glasses, however, are not known to be sensibly permeable

It was thought of interest to search for other solid materials which might have the property of passing helium far more readily than air

I have found, in fact, that sheet gelatine, celluloid and cellophane, all behave somewhat like silica glass

Silica glass and celluloid, when carefully examined in the polariscope, are found to be of the nature of crystalline mosaics, and it is likely that the helium finds its way between the crystals The same probably applies to gelatine

There is, however, an interesting field of work in examining whether helium can pass through various crystal lattices (single crystals) A few preliminary experiments have been made I have confirmed the known result that helium cannot pass through crystalline quartz, and have found further that it cannot get through mica The case of beryl is of special interest According to the analysis of W L. Bragg and J West[1] the structure of this crystal is exceptionally open, having unobstructed tunnels parallel to the optic axis, each tunnel being about the same diameter as an oxygen atom in the crystal It seemed worthy of investigation whether helium would go through I had a slice cut 0 6 mm thick perpendicular to the axis of a clear and apparently flawless aquamarine This did in fact transmit helium as indicated in the table below It is not yet certain whether the helium really passed through the lattice, or merely through flaws or cracks in it No flaws could be seen, however The test of whether air would pass through has been applied, but for technical reasons it is more difficult to be sure about the non passage of air than about the passage of helium. In any case, helium would be expected to pass through more quickly, even if the transmission were through flaws More severe tests are in progress It will be important to determine the behaviour of a slice cut parallel to the axis

Material	Transmission in c mm per day Helium	Transmission in c mm per day Air	Ratio Helium/Air
Fused silica	4×10^{-3}	—	—
Gelatine	9.23×10^{-1}	5.02×10^{-3}	185
Celluloid	39.5	1.94	20
Cellophane	1.36×10^{-1}	3.23×10^{-3}	42
Quartz cut ⊥ to axis	$< 1.01 \times 10^{-4}$	—	—
Mica	$< 2.5 \times 10^{-5}$	—	—
Beryl cut ⊥ to axis	1.34×10^{-3}	$< 2.0 \times 10^{-4}$	> 7

The accompanying table gives the main results so far. The transmission has been taken provisionally to be inversely proportional to the thickness, and the results are reduced to 1 mm thickness and 1 sq. cm area. The gas passes from atmospheric pressure on one side to vacuum on the other.

It should be mentioned that the actual figures for the organic materials are provisional, there being some evidence that the rate falls off with time This may be the effect of continued mechanical stress due to the gas pressures

Penetration of a Magnetic Field into Supra-Conductive Alloys

USING the same method as in our work on tin[1], we have investigated the behaviour of supra-conductive alloys in a magnetic field We studied a carefully prepared sample of Bi_5Tl_3 and a lead-thallium alloy containing approximately 65 per cent thallium

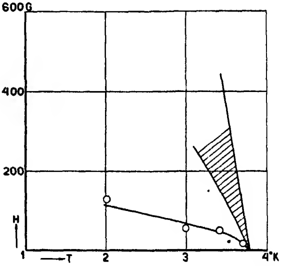

FIG 1

A cylindrical rod with a channel along its axis was made of each material, and a thin bismuth wire with current and potential wires was fitted inside this channel, we measured the change of resistance of the bismuth wire as a function of a transverse magnetic field (that is, of a field perpendicular to the axis of the cylinder). At a temperature below the transition point of the alloys, the bismuth wires did not show any change of resistance when a weak magnetic field was applied. When the strength of the field exceeded a certain critical value, a change of resistance was produced, though the alloy itself remained supra-conductive.

The value of the critical field is different for the two alloys and depends on the temperature. Fig. 1 shows the value of the critical field as a function of the temperature; in the shaded region the resistance

of the alloy is gradually coming back. In the case of Bi_5Tl_3 the result was analogous.

When the field was switched off, the resistances of the bismuth wires did not return to their normal value[2]; we have not yet determined exactly the maximum value of the magnetic field which may remain in the alloy, but it seems to be of the order of magnitude of the critical field. We are inclined to believe that the critical value of the field, that is, the value at which the field starts to penetrate into the alloy, as distinguished from the threshold field at which the resistance is coming back, may come into play in several phenomena, for example, in experiments on thermal conductivity[3].

A detailed account of the influence of a magnetic field on alloys will shortly appear in *Physica*.

Further Experiments with the Magnetic Cooling Method

CONTINUING our experiments[1] with the magnetic method, we investigated the suitability of a number of substances. The efficiency of a substance for this purpose can be defined by a characteristic temperature θ_m, which may be calculated by means of a formula which we derived under certain simplifying assumptions about the splitting of the ground state of the magnetic ions. According to this formula, the final temperature reached in demagnetising to the field zero is inversely proportional to the initial magnetic field, proportional to the initial temperature and to the temperature θ_m, characteristic for each substance, defined by $\theta_m = U/k$ (U = energy difference between the adjacent levels of the ground state, k = Boltzmann's constant). Thus, the smaller θ_m, the more suitable is the substance for attaining low temperatures.

We found that the numerical values of θ_m for the substances investigated lay between about 0.2° and 0.06°. Gadolinium sulphate[2] has the highest value; next, approximately equal, come manganese ammonium sulphate and chromium potassium alum (the substance chiefly used in the Leyden experiments[3]). Manganese ammonium sulphate, however, shows at very low temperatures deviations from the formula of a kind which suggest the existence of a Curie point slightly below 0.1°[4]. Finally follows iron ammonium alum which proved to be the most suitable of the substances we investigated. With it, for example, a temperature of 0.04° was obtained, starting at 1.25° and 14 kilogauss. Preliminary experiments with mixed crystals showed that by diluting the magnetic ions one can reduce the characteristic temperatures.

The technique was further developed, so that there is now no special difficulty in reaching the lowest temperatures, or in keeping even small amounts of substances (some tenths of a gram) at these temperatures for considerable periods. We generally chose a rate of warming up between ½ and 1 millidegree per minute.

Investigations on supra-conductivity in this region were also continued. Two further new supraconductors were found, namely, zirconium and hafnium, pure samples of which were very kindly lent to us by Dr. J. H. de Boer of the Philips Company. The transition point of zirconium lies at 0.70°, the initial slope of the magnetic threshold values being about 300 gauss per degree. In the case of hafnium we could use only a very small sample (25 c. mm.) so that the accuracy of the numerical values is not very high. Extrapolation to zero measuring field gives a transition point between 0.3° and 0.4°. Copper, gold, germanium, bismuth and magnesium, at least the samples used by us, did not become supra-conducting down to 0.05.

In investigating these metals we had still another purpose. It is to be expected that the entropy due to the random distribution of the nuclear spins will vanish within the new temperature region, where kT may be of the order of the interaction energy between the nuclear spin and the surrounding particles[5]. From their hyperfine structure (separation 10^{-2} cm.$^{-1}$ to 1 cm.$^{-1}$) it appears that the corresponding temperature for the free atoms should lie in the region between 0.01° and 1°. For compact metals nothing can be accurately predicted, but it is likely that the interaction energies will be smaller than in the gas.

By mixing a substance with a paramagnetic salt, one should be able to render observable the entropy due to the change of the distribution of the nuclear spin, since in this case one would not reach such low temperatures as with the pure salt. In cooling to 0.05°, using a mixture of equal volumes of metal and salt, one should detect these effects if the separation were greater than about 10^{-2}–10^{-3} cm.$^{-1}$. As no difference in the final temperatures which could be definitely attributed to this effect was found, it appears that the separations in the solid are lower than the limit mentioned above. In the case of bismuth this means that the separations are reduced, at least by the factor 100, on passing from the gaseous to the metallic state.

The Vortex Concept

RECENTLY Great Britain has lost two of its chief promoters (W. M. Hicks and H. Lamb) of vortical hydrodynamics, a science which was in the main line of physical suggestion forty years ago. Some historical reflections are thereby suggested.

One would think at first glance that the whole affair is implicit in a few sections at the end of Lagrange's "Mecanique", when he asserts, but without irreproachable proof, that every portion of uniform non-viscous fluid whose motion at any time involves a velocity potential continues to move subject to that restriction. For the Lagrangian principle implies that portions of the fluid mass the motion of which is vortical remain separate from the surrounding non-vortical portions. Rather, that inference ought to have come immediately to Stokes

nearly half a century later, for it was he who fortified the Lagrangian analysis and introduced vorticity or local spin as the property negated by a velocity potential But the matter was not so obvious

It was left for Helmholtz to inquire whether there could in fact be persisting motion without a potential, and to explore its laws on the basis of Riemannian continuity The motion must, as he found, be made up of filaments of spin which preserved their material identity, and which if finite must close up as rings Thus a vortex ring could be imagined as made up of adjacent threads like a hank of silk, and the question is whether they could hold together or would reduce themselves to confusion by mutual disturbance This is the question of stability of vortex motion, which gave rise to so much difficult analysis, with only limited results for cases in which facile experiment had led the way There is no limit to the thinness of the filaments, but they must not go down to molecular cross section, so that as in other molecular science the convenient terms macroscopic and microscopic claim their places, and there is no transition from fluid-theory to gas-theory

Thus a vortex ring, even though thoroughly stable, fades gradually owing to the viscidity of the molecular medium It would be interesting and valuable to consider, on the foundation also established by Stokes, whether, for example, a straight vortex cylinder fades from core outwards, and how rapidly perhaps the complex analysis involved has already been worked out The interest is mainly that in actuality a vortex ring is a carrier of momentum, and the distance it is transferred is thus an essential feature, for example, in aeronautic theory

It is needless to recall that the behaviour of vortex rings in fluid was the stimulant and earliest actual illustration of how a molecular medium could exist in and be controlled by an æther in which the molecules subsist as regions of permanent singularity

The X-Ray Crystal Scale, the Absolute Scale and the Electronic Charge

IN 1928 I published some investigations[1] on the X ray wave length of the aluminium $K\alpha_{1,2}$ line on the absolute scale, as obtained with the plane ruled grating method From this the wave-length in question came out as about 0 15 per cent higher on the absolute scale than that found by the ordinary crystal method This difference was considerably greater than expected from the stated uncertainties of the constants involved in the computation of the crystal lattice of calcite, which constitutes the crystal scale. As is well known, this result therefore was looked upon with decided scepticism

Later measurements on the same subject, of which that of Bearden in 1931[2] claims the highest precision, have secured this result The most simple way of explaining this discrepancy, namely, to ascribe it to the uncertainty in the value of the electronic charge, was systematically avoided On the contrary, the influence of the mosaic structure was suggested to give the explanation of the difference, or simply that the laws of optics were not applicable to X-rays. The first of these reasons seems to have lost its reality after the investigations of Allison[3] and Tu[4], according to which the effect of such supposed irregularities in the crystal structure is of little importance. The only support for the second suggestion seems to be the discrepancy itself which has been mentioned

However, the investigations of Allison and Tu favour the opinion that this method (ruled grating and crystal determinations combined) may even be used for a reliable determination of the electronic charge As the method has often been looked upon with some doubt, perhaps originating from the earlier inconsistent results, it seemed to me that it would be of interest to use the ruled grating method under different conditions Therefore I have carefully analysed the method and its possibilities with regard to the resolving power, the sharpness of the spectral lines, the reproducibility under different conditions, etc

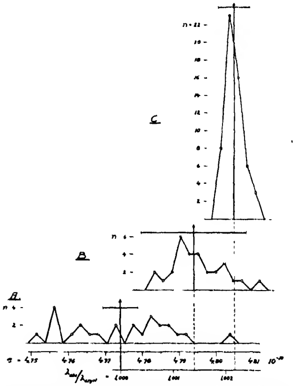

FIG 1 Diagram showing the shape of the distribution of values of e according to the measurement of (A) Millikan, (B and C) of Bäcklin in 1928 and 1934 n is number of observations within 0 05 per cent intervals

After some modifications, the precision of my former method has been very much increased, and a series of plates was taken during the month of June, 1934. The result was 56 values of the aluminium $K\alpha_{1,2}$ line up to the 5th order, the mean of which is

$$\text{Al } K\alpha_{1,2},\ \lambda = 8\ 3395\ \text{A.} \pm 0\ 012 \text{ per cent};$$

the $\pm$ indicates the arithmetical mean of the residuals. As to the reliability of this value, it may be noticed that after liberal estimation of all imaginable errors, their total sum does not reach 0 03 per cent.

The crystal value of this wave-length from Siegbahn's "Spektroskopie der Röntgenstrahlen", 1931, and corrected for diffraction (8·32135) gives the relative increase

$$\frac{\lambda_{\text{abs.}} - \lambda_{\text{cryst}}}{\lambda_{\text{cryst.}}} = 0{\cdot}218 \text{ per cent and } \frac{\lambda_{\text{abs}}}{\lambda_{\text{cryst.}}} = 1{\cdot}00218$$

corresponding to a value of the electronic charge

$$e = 4\ 805 \times 10^{-10}\ \text{E S U.}$$

instead of that ($e = 4\ 774 \times 10^{-10}$) used by fixing the crystal scale This new value is in very good accordance with Bearden's 1931 value.

For comparison with older results I have used a similar diagram (Fig 1) as before[5] showing the error distribution for Millikan's measurements and my own in 1928 and 1934 On account of the very small dispersion of the new values, the interval (within which n is the number of observations) has been diminished from 0 1 per cent to 0 05 per cent

A more detailed description will soon be published elsewhere.

Experimental Analysis of Population Growth

HUMAN populations have always proved favourite material for analysis by statisticians and others interested in mathematical theories of population growth. From the experimental aspect, however, humans are far from being ideal biological material, so that other animals, such as protozoa, mammals and insects, have to be used; although it does not yet appear to be fully realised how suitable the latter are for this type of work The theory of biotic potential and environmental resistance[1] has done much to create a new interest in population studies in that it attempts to place the problem upon a quantitative experimental basis Working with *Tribolium confusum*, Chapman demonstrated that, irrespective of the initial density, a point of equilibrium is eventually attained after which the population remains relatively constant, provided the floury medium is renewed frequently enough to remove waste products and maintain an abundance of food He concludes that equilibrium is attained when the biotic potential is equalled by the environmental resistance, and that the lack of population increase is not due to the absence of eggs or their infertility, but on account of the eating of eggs and pupæ by the adult beetles

Later, it was shown by one of us[2] that this explanation of the stationary character of the population is only partially correct, since, in the higher densities, there is a rapid falling off in the number of eggs oviposited and a considerable decrease in their fertility. At the same time, it was demonstrated for *Tribolium confusum* and *Calandra granaria* that there is an optimum density, above and below which reproduction takes place at a reduced rate. In attempting to explain this phenomenon, it was pointed out[3] that important factors were involved in "the frequency and chances of interruption of copulation in the various densities". These factors have now been analysed in detail. Our experiments show conclusively that there is a definite biological law relating frequency of copulation to population density in *Calandra granaria* and *C. oryzæ*, and that there is an 'optimum' density for frequency of copulation in these, and presumably other, insect species The data are presented graphically in Fig 1.

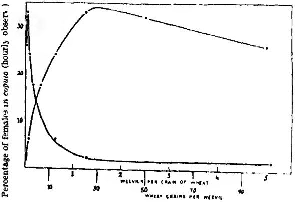

FIG 1

For densities higher than the 'optimum', our experimental data conform very closely to the theoretical relationship represented by the formula

$$\text{Log } Y = \log a + b \log X,$$

where Y is the frequency of copulation and X the number of wheat grains per weevil Further, it is apparent (see accompanying table for data) that the rate of oviposition is highly correlated with the frequency of copulation, and the latter is, therefore, a dominant factor in the rate of population growth when other factors are at or near their optimum for the species The 'optimum' densities for the above processes are not absolute and can be shifted in either direction by altering the physical or biotic factors of the environment, such as the temperature or the sex-ratio

No of Weevils	4	8	16	32	64	128	128	128
No of Wheat Grains	800	400	400	400	400	200	100	25
Weevils per grain	0 005	0 02	0 04	0 08	0 16	0 64	1 28	5 12
Grains per Weevil	200	50	25	12 5	6 25	1 56	0 78	0 19
Copulation Frequency*	22 85	31 97	33 06	24 23	17 68	5 89	2 56	1 60
Eggs per Female per day	6 75	3 52	—	3 02	—	1 60	—	0 59
Species	*Calandra oryzæ*, L Temp 25° C Rel humid 90 per cent Sex-ratio 50 50							

* Average percentage of females *in copulo* per hour

Our studies are being continued and will appear in detail later, but so far as they have gone, some important points emerge (1) In determining certain biotic constants (for example, oviposition rate) it is not sufficient to define the temperature-humidity conditions of the experiment—the density and sex-ratio of the population must also be stated. (2) In the limitation of population growth, the greater the favourability of the physical factors of the environment the less significant do they become, and (assuming absence of parasites and predators) the greater the importance of the rôle of *autobiotic* factors In Nature, these factors will be of greatest moment when the population approaches 'plague' dimensions. (3) It seems, therefore, that natural populations can exert an automatic check on their

numerical increase, and that the organism itself imposes the ultimate limit to its own abundance when all other factors normally inhibiting population increase have failed

Exhibition of 'Autogenous' Characteristics by a British Strain of *Culex pipiens* L. (Diptera, Culicidæ)

A FEW years ago, Roubaud[1], De Boissezon[2] and Huff[3] independently directed attention to the fact that females of certain strains of *C. pipiens* were remarkable, not only in being able to breed, under suitable conditions, throughout the winter, but also in being able to lay fertile eggs without a preliminary meal of blood Roubaud considers these unusual characteristics to be indicative of a distinct, 'autogenous' race of *C pipiens*, which thrives (in his opinion) exclusively in urban areas where artificially-heated buildings are common De Boissezon, on the other hand, denies the existence of such a race of *C. pipiens*, and asserts that the biological peculiarities in question may be caused to manifest themselves in any strain of *C pipiens* (whether town- or country-bred) merely by giving the larvæ plenty of rich food and keeping them warm

During the year 1932, two separate 'autogenous' strains of this species were imported into England—one, in the form of adults, from Hungary, and the other, in the form of larvæ and eggs, from Germany—and were investigated by Miss M Vincent[4] and Dr Malcolm MacGregor[5] respectively. From the material thus obtained, both of these experimenters succeeded in rearing a number of generations of *C pipiens* without providing any of the females with blood-meals The adults derived from both of the above-mentioned countries were markedly stenogamic, the German ones mating satisfactorily in cages having a volume of only one eighth of a cubic foot, and the Hungarian ones in "small cardboard tubes"

So far as we are aware, no case of autogenous characteristics being exhibited by a British strain of *C pipiens* has ever been recorded The following facts may therefore be of interest

On October 6 we found, on the surface of water in an outdoor tank (in which, it may be noted, a species of *Chara* is growing), a small raft comprising 105 eggs of *C pipiens* We transferred this raft into a laboratory tank containing ditch-water, into which crumbs of wholemeal bread were thereafter introduced from time to time The eggs composing this raft hatched on October 8, and by October 24 most of the larvæ had reached the fourth instar. Owing to the mildness of the weather throughout October, the central heating of the building was not put into action until October 31. the temperature of the laboratory during the previous four weeks having varied between 10° and 18° C.

On November 1, with the view of obtaining some freshly-hatched adults for mounting, we transferred the larvæ and some water from the laboratory tank into a small breeding-jar, which has since then been kept in close proximity to a hot-water radiator. Pupæ first appeared in the jar on November 8, and adults commenced to do so on November 12. Adults were removed from the jar when required for mounting, but in no case was a blood-meal given

On the evening of November 23 we were surprised to see a small egg-raft on the surface of the water in the jar, and we found a second one on the following morning The first raft (which consisted of 38 eggs) hatched in the evening of November 26, and the second one (of 40 eggs) hatched during that night

The portion of the breeding-jar above the water-level (that is, the space in which the adults are confined) has a volume of 600 c c—about one-sixth that of the cages employed by MacGregor

Do Whales Descend to Great Depths?

As I have stated elsewhere[1], a difference of opinion exists as to the depth to which whales descend. Diver's paralysis or caisson disease is the usual consequence of descending below about 130 ft. Do whales descend below this depth? For obvious reasons, the answer to this question is of considerable interest from a physiological point of view

Quite a number of awkward facts might be presented to those who, on theoretical grounds, deny that whales descend below very moderate depths Perhaps the following will suffice

1 The whaling ships that used to sail from Dundee and Peterhead each carried a number of five-oared boats and several miles of 2¼-in or 2½-in. whale-line, and when the ships reached the ice, 600 fathoms of whale line were coiled into each of the boats It was, however, only in the deeper parts of the Greenland Sea and Davis Strait that it was necessary to coil so much line into the boats. as may be gathered from what Scoresby says, in shallow situations near Spitsbergen and the west coast of Greenland where the whales were caught at an earlier date, a shorter length of line sufficed

2. When a harpooned Greenland whale 'sounded', or went vertically down, it took out the whale-line very quickly; the wooden bollard in the boat's bow sometimes smoked and threatened to catch fire At the same time, the boat's bow was pulled down, and if, as sometimes happened, the line became entangled, the boat was liable to be pulled right down. After an interval the whale reappeared near where it went down and was killed

3. When harpooned whales 'sound' they take out a limited amount of line only.

(*a*) Large Greenland whales took out from 700 to 800 fathoms; half-grown animals from 400 to 600 fathoms, and calves apparently very much less.

(*b*) A full-grown male Bottlenose took out 700 fathoms; females and young males from 300 to 400 fathoms.

(*c*) Large narwhals took out about 200 fathoms.

Except in the vicinity of certain kinds of ice, Greenland whales when harpooned nearly always sounded or dived towards the bottom. What kind of refuge they expected to find at the bottom is not very apparent. Sometimes they died at the bottom

and had to be hauled up, occasionally, according to Scoresby, with broken jaw-bones. A log book, dated 1871, now in the Hull Museum, contains the following entry: "June 25th (Lancaster Sound): Killed a whale which died at the bottom in 600 fathoms of water".

Vision in the Ultra-Violet

WITH regard to the discussion which has been taking place in NATURE recently[1], the following observations may be of interest. In 1929, whilst working at the National Institute for Medical Research, Hampstead, with T C Angus, in the course of which we used, incidentally, a double monochromator, and whilst we were fitting this up, we decided to try on ourselves how far we could see into the ultra-violet. We decided that one of us could see the λ3130, and the other could not see shorter than λ3650 in the mercury spectrum. Another young physicist could see λ3130 quite easily. An elderly man could only see λ3650.

I have just repeated these observations. I can see λ3130 quite easily, as can an assistant of mine and a youth who works in the clinic. Only a single monochromator was used for this purpose; this is a Hilger monochromator for the ultra-violet, and as Fabry[2] says, there is always a certain amount of background but this remains constant as the wave-length drum is rotated slightly. This later procedure brings the line on to and removes it from the collimator slit. Thus the line can be picked out against the background. The λ3130 line appears as a dark violet colour much the same as λ3650. Since people varying from fifteen to thirty years of age are able to get the sensation of sight with λ3130, it does not seem to be the prerogative of extreme youth.

Oxidation-Reduction Potentials of Hypoxanthine ⇌ Xanthine and Xanthine ⇌ Uric Acid

IN a recent paper, D. E. Green[1] published values of the potentials of the systems hypoxanthine ⇌ uric acid, xanthine ⇌ uric acid, which I had already determined[2].

Green claims to be the first to have demonstrated the reversibility of the system hypoxanthine ⇌ uric acid. He states this, because my data are based on measurements made on equimolecular mixtures of hypoxanthine and uric acid, and consequently the constancy of the normal potential when the proportions of the constituents of the system are varied is not evident. Green asserts this, in spite of the fact that I have shown that the same state of equilibrium (the same potential) is found, whether hypoxanthine is oxidised, or uric acid is reduced. It seems to me then that the curve presented in my work leaves no doubt as to the reversibility of the system.

Green also states that I did not justify the assignment of the value of the number of equivalents in the formula

$$E_h = E_0 - \frac{RT}{4F} \ln \frac{[Hx]}{[U]}$$

where E_0 is the normal potential, $[Hx]$ the activity of hypoxanthine, and $[U]$ the activity of uric acid. It is, however, not at all difficult to see that if the reaction taking place in the galvanic cell is an oxidation of hypoxanthine into uric acid, and that this reaction is reversible (as I have shown it to be), then it follows that the above equation is a necessary consequence of thermodynamics. I did not consider it useful to insist on its validity in a preliminary note. Moreover, this equation does not at all imply equality of the levels of energy at which the four hydrogens are exchanged, since only the initial state and the final state of the constituents of the reaction are to be taken into consideration.

Finally, if I have neglected the dismutation discovered by Bach and Michlin, I have done so because Wieland was not able to confirm their findings. I quite agree with Green that the short duration of Wieland's experiments may explain why the dismutation of xanthine to hypoxanthine and uric acid was not observed. But I should like to point out that if such a dismutation does exist (in any proportion whatsoever), it would not at all affect my results since the ratio $[Hx]/[U]$ remains equal to 1 when two molecules of xanthine are formed at the expense of one molecule of hypoxanthine and one molecule of uric acid.

Thus, no objection could be made as to the value, which I found for the normal potential of the system hypoxanthine ⇌ uric acid. It is

$$E'_0 = -0.410 \text{ volt at } 38^\circ \text{ C and at } pH = 7.31$$

(value calculated from my data), or

$$E'_0 = -0.399 \text{ volt at } 30^\circ \text{ C and at } pH = 7.31$$

(value calculated from the temperature coefficient that I have later established).

This value is identical with the theoretical one given by Green, namely, − 0.400.

As for the system xanthine ⇌ uric acid, the dismutation does bring about a correction for the value of E'_0 but it is inferior to the experimental errors if Bach and Michlin's figures are used. If, however, we apply the method of calculation that Michaelis has shown in his well-known work on two-step oxidations, and making use of Green's figures, we arrive at a new value for the dismutation constant. This value should be taken into consideration, although the resulting variation, when applied to equimolecular mixtures, is rather small.

Applying this correction, the value of the normal potential of the system xanthine ⇌ uric acid will then differ from the one that I have indicated by − 0.0048 volt at $pH = 7.65$.

D. E. Green's confirmation of the existence of a dismutation process is therefore of interest. It entails a correction of the same order as the one brought about by the ionic concentration effect, which I have studied in detail in a memoir actually in press.

Flavin Transformation by Bacteria

FROM a lactoflavin solution which had become blue fluorescent, a bacterial species has been isolated capable of changing the usual green fluorescence of the flavin solution, and of developing a blue fluorescence When a very small amount of these bacteria, taken from agar, is put into each of two tubes, one containing aqueous flavin solution, the other only water, the following observations can be made

1 The green fluorescence of flavin often disappears in about an hour, due to reduction, and may be recovered by shaking with air

2 In any case the intensity of the green fluorescence becomes gradually less At the same time a blue fluorescence develops in the solution The final disappearance of flavin takes about 12 hours with fresh bacteria and 0 6 γ per c c of lactoflavin More than 3 γ per c c of lactoflavin in the solution is toxic, and no change occurs

3 The tube containing water and bacteria, but no flavin, does not develop a blue fluorescence No visible growth occurs in either tube

4 A tube containing the same amount of flavin under sterile conditions continues to fluoresce green indefinitely

Brewers' yeast and *Clostridium acetobutylicum*, both of which contain flavin, do not effect a similar change in flavin solutions, nor does *Mycoderma cerevisiae* The bacteria concerned, after drying, give an alcoholic extract showing no green (flavin) fluorescence, but only blue

The blue-fluorescing substance, either extracted from the bacteria or formed in a flavin solution by a small amount of bacteria, is extractable by chloroform It may be extracted from chloroform by alkaline water. The blue fluorescence has the same intensity from pH 12 to pH 5, but disappears in more acid solutions It is not affected by hydrosulphite, or by bromine

The organism is a Gram-negative rod, occurring in pairs (diplo), and apparently non spore forming a possible relationship to Coli bacteria is being investigated

The nature of the blue fluorescing substance, and of its apparent production from flavin by this and other organisms, is being studied The wide distribution of lactoflavin in Nature, and the existence of a related, blue-fluorescing substance (lumichrome), give these observations special significance

Cosmic Radiation and Stellar Evolution

IN connexion with the recent hypotheses[1] that some of the components of the cosmic rays are ions, it may be noted that the emission of high speed ions from stars would reduce their mass by the same amount as if these ions had been annihilated in the manner suggested by Jeans. The emission of a proton from a star represents the same loss of stellar mass as the transformation of a proton and an electron into a quantum of ultra γ-radiation.

Thus the emission of cosmic radiation in the form of heavy ions from stars may reconcile the theory of stellar evolution suggested by Eddington's mass luminosity law and the Russell diagram (which seems to require stellar lives of the order only possible if we assume an Einstein-de Sitter universe with a time scale of 10^{12} years), and the Friedmann-Lemaître cosmology with an expanding universe, which suggests that the age of the stars is of the order 10^{10} years, for the emission of heavy ions in such intensity as is indicated by the cosmic ray ionisation observed at high altitudes suggests that stellar mass may decrease appreciably during 10^{10} years, since in addition to the loss of mass due to the emission of heat and light radiation, there is the decrease due to the actual ejection of stellar ions probably of high mass.

The process of stellar evolution in the downward direction of the Russell diagram would thus suggest (if the short time scale of the expanding universe is adopted) that the cosmic ray ions are mainly emitted from the heavier stars; and by main sequence stars in passing down the sequence According to this suggestion, the low mass of the white dwarfs (which are usually assumed to represent the final stage of stellar evolution) shows, therefore, that cosmic rays are entirely emitted *from the younger stars, and* it is probable, therefore, that the white dwarfs emit practically no radiation in the form of cosmic rays

Formulæ and Equations in Nuclear Chemistry

IN the advance proofs of the International Conference on Physics, held in London and Cambridge in October 1934, and in other recent publications, the Italian authors write the mass-number and atomic number of the element on the right; for example, $He_2{}^4$, $Cl_{17}{}^{35}$; the English authors write them *diagonally*, for example, $_2He^4$, $_{17}Cl^{35}$, and the French authors on the left, thus, ${}^4_2He$, ${}^{35}_{17}Cl$ When dealing with molecules it is essential to leave a space on the right in which to indicate the number of atoms as in the English formulæ, H_2O, Cl_2, or the French formulæ, H^2O, Cl^2, etc The Italian scheme blocks both positions and cannot be used by chemists, the English scheme cannot be used by French chemists, whereas the French scheme is convenient for all nationalities and might with advantage be adopted internationally. It has the incidental advantage that, when the numbers are printed vertically above one another, and are not staggered as in the Italian scheme, it is particularly easy to see by subtraction the number of neutrons in the nucleus.

A New Magnetic Alloy with very Large Coercitive Force

WHILE investigating the magnetic properties of metallic neodymium containing about 7 per cent of iron (the sample was kindly lent to us by Prof. Hopkins of Urbana, Ill.) we found that this material is strongly ferromagnetic. Its specific magnetisation

(near saturation) in a field of 20,000 Oersted is about 13 at room temperature.

It is rather difficult to assert at present whether we are dealing with a homogeneous alloy of iron and neodymium, or whether the finely dispersed iron is imbedded among the neodymium grains. The value of the specific magnetisation seems to correspond to about 7 per cent of free iron. Yet the material investigated by us shows an extraordinarily great coercitive force, reaching 4,300 Oersted with a remanent magnetisation equal to 70 per cent of the maximal temporary value. This enormous coercitive force, so far as we know, has never been observed either in pure iron or in any of its alloys. Thus we may conclude that these remarkable magnetic properties are due to a hitherto unknown iron alloy.

We are examining the nature of this alloy and we hope to publish soon elsewhere further details concerning this problem.

Ascorbic Acid and Thiosulphate in Urine

To investigate the metabolism of vitamin C, one can determine the content of ascorbic acid in urine by means of titration with 2 . 6 dichlorophenolindophenol in acid medium. An interfering reducing substance is present in relatively large amount in the urine of diabetics and also in that of cats, and to less extent in the urine of normal persons and dogs; this has proved to be thiosulphate.

The thiosulphate can be separated from the ascorbic acid by means of precipitation with mercuric acetate (a method used to remove cystein, ergothionein and glutathion[1,2]) and by precipitation with barium salts.

Details of the operation will appear in *Acta Brevia Neerlandica*.

Points from Foregoing Letters

LORD RAYLEIGH finds that helium gas can pass not only through silica glass but also through gelatine and celluloid. He suggests that the gas passes between the individual crystals that compose these materials. Single crystals of quartz do not allow the passage of helium, but beryl, which has an exceptionally open crystal structure, does.

Alloys of thallium-lead or thallium-bismuth (Bi_5Tl_3) when rendered supra-conductive by cooling below 4° K., allow electromagnetic fields above certain critical values to penetrate them. Prof. W. J. de Haas and Mr. J. M. Casimir-Jonker give the relation between the value of the critical electromagnetic field and the temperature.

Experiments with supra-conductive materials are also reported by Mr. N. Kurti and Prof. F. Simon, who have determined the transition points for zirconium (0·70° K.), hafnium (0·3–0·4° K.) and other metals. From these experiments and others with mixtures of a metal and paramagnetic salt, the authors hope to observe the effect (entropy) due to the change of distribution of the spin of atomic nuclei at very low temperatures (0·01°–1·0° K.). The authors, using the magnetic method of producing very low temperatures, have reached a temperature of 0·04° K. with iron alum.

The recent deaths of Prof. W. M. Hicks and Sir Horace Lamb prompt Sir Joseph Larmor to contribute a few historical remarks on vortex theory, and to direct attention to one of its unsolved aspects of importance to aeronautic research, namely, whether a straight vortex cylinder fades from core outwards, and how rapidly.

From calculations based upon the wave-length of X-rays determined by the grating method, and also from crystal diffraction, Prof. Erik Bäcklin finds a value for the charge of an electron which differs appreciably from that obtained directly by means of electrified droplets.

Experiments on the relation between density and frequency of copulation in weevils lead Dr. S. MacLagan and Mr. E. Dunn to the conclusion that the organism automatically limits its own abundance, when other factors normally inhibiting population are not effective.

Certain mosquitoes (*Culex pipiens*) of British origin can lay eggs without a previous meal of blood. Mr. J. F. Marshall and Mr. J. Staley report this fact, already observed with certain races of mosquitoes on the Continent, and ascribed to their adaptation to urban areas, where artificially heated buildings are common.

The electro-chemical potential (electromotive force) obtainable from the oxidation of hypoxanthine to uric acid (final stage of nitrogen compounds eliminated from the body brought about in the presence of enzymes existing in the liver, spleen and in milk), was found by Miss Filitti to be about − 0·400 and − 0·113 volts respectively. Mr. D. E. Green went more deeply into the theory of the reaction, and carried out further experiments, criticising previous work as not proved. Miss Filitti now points out that, as regards hypoxanthine, Green's findings confirm her own, while the xanthine-uric acid potential needs only a small correction due to their 'dismutation' (reversible change in absence of oxygen).

A bacterium which is able to destroy the usual green fluorescence of flavin solutions, producing instead a blue fluorescence, is brought to notice by Dr. L. Bradley Pett, who describes some of the properties of the blue fluorescent substance.

The theory of the expanding universe gives ten thousand million years as the age of the stars, while previous calculations based upon the rate of loss of mass (in the form of energy) necessitated a period a hundred times longer. Mr. H. J. Walke suggests that the discrepancy would be eliminated if the heavier stars give off not only radiant energy but also ions (which form part of the cosmic rays).

Neodymium containing 7 per cent of iron is found by Miss V. Drožžina and Mr. R. Janus to have great power of retaining magnetisation. The reversed magnetic field necessary to reduce its magnetic induction to zero (coercive field) is stated to be greater than that for pure iron or any of its known alloys, which suggests that the material investigated contains a hitherto unknown iron alloy.

Research Items

Population of Europe. Some comparisons of density and distribution of European population in 1720, 1820 and 1930 are made by Mr. J. Haliczer in *Geography* of December 1934. The data for 1720 involve various calculations back from later years and contemporary estimates. Those for 1820 include census figures for most of the States of Western Europe but, as in 1720, no data of any value are available for the Balkan peninsula. In 1930 reliable census figures are used. So far as comparisons are valid, Mr. Haliczer computes that the population in 1820 was 1·89 times that in 1720 and in 1930 it was 4·51 times that of 1720. Two centuries ago the population everywhere was sparse except in the Rhine valley, central Germany, the English plain and the Po basin. The regulating factor of chief import was then soil fertility, but the black soil area of southern Russia was almost empty. By 1820, the ranges between maximum and minimum densities were small, but industrialised areas were beginning to show marked increases. The peopling of the black earth region was beginning. By 1930 inequalities in density were very marked owing to industrialism, and in Russia the 'centre of gravity' of population had shifted south. A further estimate shows that in 1720 the 'centre of gravity' of Europe's population was about 45 miles east of Munich, in 1820 it was 14 miles east of Passau and in 1930 it had moved to 30 miles north of Vienna. In other words, it has shown a steady tendency to move east, thus decreasing the percentage of the whole population that inhabits western Europe. The total shift in two centuries is 124 miles.

Life-History of *Euphausia krohnii*. Miss Winifred E. Frost has described the occurrence and development of *Euphausia krohnii* off the south-west coast of Ireland (*Proc. Roy. Irish Acad.*, 42, (B), No. 3, 1934). Already in a previous publication (1932) she has considered the distribution of the larvæ of *Meganyctiphanes norvegica* and *Nyctiphanes couchii*, and the present paper is on the same lines. *Euphausia krohnii* is one of the species of euphausiids most frequently taken in these waters, and the adults occur in large numbers. It is interesting that Miss Frost finds the same number of furcilia stages which occurred in Mr. F. S. Russell's material from the Mediterranean (Lebour, 1926) and only these, three in all. No intermediate forms have ever been described, and this indicates the probability of the 'jumping' of several stages, which is apparently not unusual in deep-sea species. Eight cyrtopia stages are described which gradually lead to the adult form. This species is only found in waters of high salinity and is a typical oceanic species. Its normal habitat for living and breeding is on, and westward of, the Atlantic Slope. All the present material, with one exception, came from a depth of more than 100 fathoms, although some of the Mediterranean larvæ were found in only 17 fathoms. They are always found in water of a fairly high temperature. Breeding appears to take place almost throughout the year, with varying seasonal intensity.

Effect of X-Rays on a Sex Cell of Tobacco. In an investigation of the effects of X-rays in producing mutations in *Nicotiana Tabacum* var. *purpurea*, Goodspeed and Avery (*J. Genetics*, 29, No. 3) treated the megaspore mother cells to radiation at about the time of the reduction divisions. The resulting progeny showed a large series of variations. One of these was crossed with the control and the offspring were bred through five generations. In this way were obtained from the descendants of a single X-rayed megaspore 14 derivative types, 7 of which bred true. These types differed from the control in habit, form of leaf, flower and capsule, and in colour of leaf and flower, some of the types being so marked that they would rank as varieties or even species. Two types shown to be due to different genes bore stigmatoid anthers, another had pointed capsules, while the leaves ranged from broadly ovate to elliptic and the flower colour from carmine to rose and orange-red. Cytogenetic analysis showed that at least five of the 24 haploid chromosomes had been altered. Chromosome fragmentations had occurred, leading to homozygous duplications and deficiencies, as well as translocations and gene mutations. Probably plants which are homozygous for a chromosome deficiency can survive because the tobacco is a polyploid species.

Sclerotinia Rot of Patwa in India. Patwa (*Hibiscus sabdariffa*) is a fibre crop grown fairly extensively round the Pusa district of Bihar, India. It is sown with the monsoon rain in July, and is usually harvested for fibre in late October. A few plants to provide seed, however, are left until the end of February. The appearance of a destructive disease in December and January is therefore a serious menace to the continued propagation of the crop. Dr. B. B. Mundkur has studied this disease (*Indian J. Agric. Science*, 4, Part 4, 758–778, August 1934). The fungus attacks the flowering stem, causing brown patches or cankers to appear on the surface. Black sclerotia may also appear, and frequently are found in the seed bolls. They are about the size of Patwa seeds, but are easily distinguished by their colour. The causal fungus has been identified as *Sclerotinia sclerotiorum* (Lib.), de Bary. Ascospores are produced from apothecia lying on the soil in November, and can infect unwounded, healthy plants. The optimum temperature for growth is 22° C. Hand separation of sclerotia from harvested seeds, combined with deep ploughing to bury sclerotia which may lie on the surface, are the control measures recommended.

Advance of Glaciers. In a recent paper to the Royal Geographical Society (November 19) on "Threatening Glaciers", Prof. K. Mason reviewed the evidence available regarding the movement of glacier snouts in the Karakorams during the last twenty years. He believes that substantial advance of the snout follows a period of degeneration or retreat, and that the rate of advance is controlled by topography. After the advance the snout takes some time to settle and if unenclosed is liable to spread. The variations in the dates of advance of various contiguous glaciers suggests that the advances cannot be due to climatic cycles. With some glaciers, periodic rapid advances occur. Prof. Mason thinks that these advances are due to accumulations of ice in the

gathering ground either by avalanches, the advance of tributary glaciers or by normal snowfall. The accumulation is slow, and the outflow may be obstructed, but eventually the pressure becomes irresistible and the glacier advances In discussing what could be done to mitigate disasters due to ice advances and associated floods, Prof. Mason believes the best plan is to study the intermittency of the glacier and so be able to predict its advance If the causes are of the nature he suggests, no doubt the advances and retreats are rhythmical.

A Forgotten Indian Meteorite. In his presidential address to the Hyderabad Science Association in July last, Mohammad A. R. Khan, principal of Osmania University College, Hyderabad, directs attention to a recorded fall of a meteorite which was omitted from C. A Silberrad's "List of Indian Meteorites" (*Min. Mag*, **23**, 290; 1932) The circumstances of the fall referred to were recorded at the time by Jahāngīr in his memoirs, of which several translations are available The meteorite fell in one of the villages of the Jalandhar district, Punjab, in 1621 (30 Fawardin, A.H 1030) and was brought to the Emperor Jahāngīr, who ordered a sword, a dagger and a knife to be made out of it The sword-maker found that the meteorite broke to pieces under the hammer, whereupon he was told to mix it with some other iron. This he did, using 3 parts of meteorite to 1 of 'common iron', and made two sword blades, a knife and a dagger, and brought them to Jahāngīr, who found they cut splendidly The fact that the swords had been made was known to James Sowerby, who, in 1820, published in the *Philosophical Magazine* an account of a sword which he had made in 1814 for Alexander, Emperor of Russia, out of a piece of the Cape of Good Hope meteoric iron. In this instance, the blade was made from the meteorite without any admixture of other metal. It has been suggested by H. Blochmann that the Jalandhar meteorite was a stony iron or siderolite, and not a true meteoric iron, since it broke to pieces under the hammer. Its weight is given as 160 tolas (about 2 kgm.). Mr. Khan has published his address in an abridged form hoping to induce some of his readers to inquire as to the present whereabouts of the swords made from this meteorite. In an appendix he has collected published accounts of a recently recorded fall of meteoric iron at Bahjoi, south of Moradabad, United Provinces, on the night of July 23, 1934. One piece, the only one so far recovered, weighs nearly 23 lb.

Infra-Red Spectrum of Iron. The production of photographic plates sensitive to infra-red light has been of great value in the study of this part of the spectra of both laboratory and other sources. It has also, however, emphasised the need for accurate wave-lengths which can be used as a comparison in this region. The iron arc is a very convenient source of comparison spectra for most types of work, but the wave-lengths in the infra-red have not been satisfactorily studied. This has now been remedied by Prof. H. Dingle (*Mon. Not. R.A.S.*, **94**, 866) who has measured the wave-lengths of 68 lines between 8838 A. and 10219 A. The photographs were obtained in the first order of a 10-ft. concave grating, the overlapping second and third orders being used as comparisons for determining wave-lengths. The results are not proposed as ultimate standards, but are probably correct to within 0 01–0 02 A, and should be found of great value to those engaged in infra-red investigations.

Liquefaction of Helium. The liquefaction of helium, using the Joule-Thomson cooling effect, is ordinarily a costly process requiring large quantities of liquid hydrogen for pre-cooling P. Kapitza (*Proc Roy. Soc*, Nov. 1, 1934) has succeeded in liquefying helium by adiabatic expansion, the expanding gas being made to do external work on a moving piston The difficulty of lubricating a piston working at very low temperatures is surmounted by making the piston fit its cylinder fairly loosely The loss of helium past the piston is reduced by making the expansion stroke very quickly, and the work is done against hydraulic pressure The temperature is reduced in this engine to 10° *K* and the gas is finally liquefied by expansion through a nozzle, using the Joule-Thomson effect Liquid air only is used for pre-cooling and when the apparatus is working, 2 litres of liquid helium are produced per hour, with a consumption of 3 litres of liquid air (see also NATURE, 133, 708, 1934) This apparatus marks a very important advance in the technique of low temperatures

Active Chlorine. Various workers have found that an abnormally active form of chlorine is produced by an electric discharge in the gas E. J. B Willey and S G Foord (*Proc. Roy Soc*, A, Nov. 15) have repeated and extended this work under more carefully defined conditions. No pressure change was observed when an enclosed mass of chlorine was subjected to the silent electric discharge in an ozoniser, and no special optical absorption could be detected in the treated gas. The chemical reactivity was tested in several different ways. A marked increase in the reaction with water was observed when the chlorine was activated by a silent or spark discharge. The chlorination of benzene, both substitutional and additional, was used in much of the work as an index reaction It was found that the activity was not produced without the presence of a small quantity of impurity, possibly a trace of water or hydrogen chloride. The experiments on this point were inconclusive, but it was thought that the reactivity is genuinely due to chlorine and not to a reactive impurity.

New Methods in Stereochemistry. The purification of crude *d*- or *l*-borneol, obtained directly from natural sources or by reducing *d*- or *l*-camphor, usually falls into two stages: (*a*) the separation of borneol from isoborneol, and (*b*) the stereochemical purification of the resulting borneol. J. Clark and J. Read (*J. Chem. Soc.*, 1773; 1934) now show that crude *d*- and *l*-borneol may be effectively purified by a species of auto-catalytic process Thus, a specimen of commercial *d*-borneol was converted into impure *d*-bornylacetic acid; the impure *d*-bornyl *d*-bornoxyacetate obtained by esterifying this acid with some of the original *d*-borneol yielded stereochemically pure *d*-bornyl *d*-bornoxyacetate when fractionally crystallised; and upon hydrolysis this ether-ester yielded pure *d*-borneol and pure *d*-bornoxyacetic acid In a similar way, pure *l*-borneol and pure *l*-bornoxyacetic acid were prepared from a specimen of commercial *l*-borneol. The method permits also of the preparation of stereochemically pure *l*-camphor from commercial *l*-borneol.

Physical Society's Exhibition of Scientific Instruments and Apparatus

THE Physical Society's twenty-fifth annual Exhibition of Scientific Instruments and Apparatus was held at the Imperial College of Science and Technology on January 1–3 It is interesting to recall that the first exhibition organised by the Society was held in the same College in 1905, and, except for the War period, it has been an annual event of outstanding importance in the scientific world Perhaps it is not too much to say that it provides the regular milestones for British scientific instrument manufacturers, much in the same way that the annual motor show does for the automobile industry.

In 1920 the Optical Society joined the Physical Society of London at these exhibitions, and in 1932 these two bodies amalgamated under the title of "The Physical Society". The first exhibition was open for one evening only and there were 17 exhibitors, nearly all of whom are numbered among the 110 organisations that took part in this year's exhibition In 1926 the Research and Experimental Section was added, it was divided into three groups The first, Group A, was intended to show "typical results of recent physical research of general interest and examples of new and improved laboratory methods", the second, Group B, was to include "little known and effective lecture experiments of interest to teachers of physics", while the third, Group C, was to provide an "opportunity for demonstrating repetitions of famous historical experiments in physics". This last group was discontinued in 1931

Largely at the instigation of the exhibitors themselves in general meeting, an annual competition in craftsmanship and draughtsmanship for apprentices and learners employed by exhibiting firms is now organised in connexion with each exhibition, and money prizes to the value of over £40, as well as certificates of honourable mention, are awarded each year The work submitted is exhibited in a special section Mr R W Paul, who has done so much to establish these competitions, writing in the February 1934 issue of the *Journal of Scientific Instruments*, says. "At present the principals of some of our leading concerns appear to take no active steps to encourage their apprentices to compete in the Craftsmanship Competition, so that the interest taken in the workshops varies greatly. Obviously the provision of facilities for executing the simple job which suffices to show an apprentice's skill involves some altruism on the part of a firm for the benefit of the industry, but regard should be had to the beneficial effect on the workers of the spirit of emulation aroused and the good effect on the morale of the shops The stimulus given by the competition to candidates is known in many cases to have had a beneficial effect on their careers. Further, it is believed the competition does something to raise the international status of our instrument trade"

The problem of providing the ever-increasing accommodation and supplies of electrical power necessary is one which, for the past few years, has taxed the ingenuity of those responsible. But with the valuable help of the College authorities and the co-operation of the exhibitors, it has been possible to arrange matters satisfactorily, although perhaps not ideally It must be remembered, however, that the Society receives the great privilege of free accommodation in the College, often at considerable inconvenience to the academic and research staffs No charge is made to exhibitors for their stands, who only participate at the invitation of the Society, and it is this feature among others which makes these exhibitions so different from the ordinary trade exhibitions Another noteworthy feature is that, in a very large number of instances, the directors and leading technical experts of the firms exhibiting are in attendance on the stands, so that competent replies are received to those highly technical questions which those genuinely interested must of necessity ask

The catalogue is now issued about a fortnight before the exhibition opens, and it is valuable as a handbook to be kept on the desk until the next issue appears Most exhibitors give a brief description of the principles underlying the action of the instruments and it is this that renders the catalogue so helpful A limited number of copies is still available and may be obtained from the office of the Society at the Institute of Physics, 1 Lowther Gardens, South Kensington, S W 7 (1*s* post free)

The Committee of the Society responsible for the organisation of these exhibitions strongly endorses the view of the Institute of Physics that it is desirable that firms and research organisations taking part in exhibitions organised by scientific societies should include the names of individuals associated with each of the exhibits. The entries in the catalogue for the past few years have displayed a desirable improvement in this respect, and credit is usually given to the designer and others responsible for the development of the various individual exhibits

Among the devices in the trade section this year were many examples of recent developments and improvements in electrical indicating instruments, galvanometers, radio instruments, relays, pyrometers, thermostats, humidity measuring apparatus, meteorological instruments, microscopes, projection and cinema apparatus, in addition to recorders, controllers and motors for numerous purposes. Representative collections of new technical books and journals were also shown. The recent rapid development of acoustics was represented by several exhibits, and the number of new illumination meters and applications of rectifiers which were shown was worthy of note In the limited space available here it is impossible to mention individual exhibits shown in the trade section, so many of which appeared to be of special interest and importance. Descriptions of the exhibits may be found in the various trade journals, in the catalogue of the exhibition, and in the February issue of the *Journal of Scientific Instruments*, which is devoted each year to accounts of the most important new devices shown in the various sections; summaries of the discourses will also be included in that issue of the *Journal*. We must be content here with brief reference to a few typical exhibits, which are mentioned for no other reason than to indicate the wide variety of instruments and apparatus shown. These are: an apparatus intended for the detection of cracks in iron or steel by local magnetisation; a device for determining the ripeness of fresh tomato juice; an electrical instrument for determining whether hunting by scent on any particular day is likely to be satisfactory; a special red

light without heat for stimulating plant growth, and, of course, numerous examples of more ordinary instruments in new and improved designs

The Research and Experimental Section provides always a fascinating display of the research physicists' work before it reaches the commercial production stage Thirty-one of the research laboratories attached to Government departments, research associations, universities and manufacturing firms exhibited. Many of the devices shown had been developed for testing the properties and behaviour of a wide variety of materials under the differing conditions met with in practice, whilst several others were concerned with applications of cathode ray tubes and electron cameras to all manner of problems One exhibit was staged to demonstrate the possibilities of ordering a number of different materials to match a given colour by quoting a standard name, number or code word, and another was designed for the routine measurement of the colour values of fabric and similar surfaces viewed by diffusely reflected light. Developments in the method of controlling the speed of small electric and mechanical motions by means of light tuning forks formed the subject of another exhibit Others were, a galvanometer which is said to be immune from mechanical disturbance of the zero, despite violent pitching and rolling of the type met with in marine work, and a high speed motion picture timing system and camera which is said to take as many as 2,500 pictures a second

Radio and telephony formed the subject of several important exhibits in the Research Section, and among these mention may be made of a standard receiver for the measurement of radio interference, a map of England and southern Scotland showing the electrical resistivity of the earth, and an 'artificial mouth' for testing telephones

The growing use of discharge tubes for illumination purposes has led to the development of various devices for studying their behaviour, and some of these were exhibited Another illumination device shown was a gas burner for producing an intermittent flame or light

On each evening of the exhibition a discourse was delivered. The first was entitled "The Architecture of Molecules" in which Dr B Wheeler Robinson gave an account of recent X ray investigations of molecular structure made at the Davy-Faraday Laboratory and elsewhere, the second was delivered by Dr C V Drysdale on "The Problem of Ether Drift", a subject which readers of NATURE will know he has recently taken up with characteristic zeal, and on the third day, when the public is admitted to the Exhibition, the Astronomer Royal spoke on "Giant Telescopes".

The attendance at this year's Exhibition is not yet known, but in the past two years it has wanted but a few hundreds to be ten thousand. The Society is justly proud of the record of service it has rendered for so long to all those concerned with instruments, to the instrument industry in Great Britain, and to the public

HERBERT R LANG.

Biochemistry of Marine Phytoplankton

A SERIES of papers on "Observations on the Fatty Constituents of Marine Plankton" (*J. Exp Biol.*, 11, 173–197, 198–202, 203–209, 1934) sheds considerable light on the content of fat and vitamins A and D in plankton, on which all marine animal life is dependent directly or indirectly for existence.

In Part 1, on the "Biology of the Plankton" by E. R. Gunther, in order to convey a more precise idea of the relative importance of each species, an attempt is made to translate by means of suitable measurements the figures representing the numbers of a species present in a given quantity of plankton into figures representing the volume occupied by that species. The oil content of May phytoplankton from near the Isle of Man was about 6·9 per cent on the dry weight, and it is suggested that the oil content may vary with the species and fluctuate during the life-history. The oil content of July zooplankton varied between 15 and 19·3 per cent. In plankton giving a high oil yield, *Calanus finmarchicus* was very prominent.

In Part 2, on the "General Character of the Plankton Oils", G. Collin, J. C. Drummond, T P. Hilditch and E. R. Gunther show that the fatty acid fraction of the zooplankton oils resembled that from fish liver oils In the non-saponifiable fraction they demonstrated the presence of cholesterol, cetyl and eicosenoyl alcohols, a hydrocarbon suggestive of squalene and possibly batyl alcohol.

In Part 3, on "The Vitamin A and D Content of Oils derived from Plankton", J C. Drummond and E R. Gunther describe the results of an examination of the oils by feeding tests, with antimony trichloride and spectroscopically They show that the phytoplankton oil is more potent than the zooplankton oil in its growth-promoting action, and this is correlated with a greater richness in lipochrome pigments related to carotene Vitamin A as such is apparently absent from both phytoplankton and zooplankton. In testing for vitamin D, the degree of healing was determined both by histological (line test) and by X-ray examinations In daily doses of 50 mgm., phytoplankton oil showed no antirachitic activity but zooplankton showed slight activity. It is suggested that the small amount of vitamin D present in the animals results from their irradiation while in surface waters rather than from a prolonged diet of phytoplankton.

Building in Earthquake Countries

WE have received from Dr C. E. Adams, Dominion astronomer and seismologist in New Zealand, several papers by Mr. R. W. de Montalk In these, the author, who is an architect, describes a foundation, called the 'Salvus' foundation, that he has devised in order to lessen the effects of destructive earthquakes It consists of a platform fixed to the ground. This is made of reinforced concrete, the under side of which may be strengthened, if necessary Round the edge of the platform rises a rim of the same material, which contains a layer of clean fine shingle, 4–11 in. in depth according to the weight

of the building. On this rests a slab, also of reinforced concrete, the foundation proper of the building, a space of about 4 in. being left between the walls and the inner edge of the rim

When an earthquake occurs, the platform and shingle move with the earth under the building, which, not being fixed to the ground, tends to remain still. It is claimed that the 'Salvus' foundation not only saves the building from damage or destruction, but also lessens the risk of fire during an earthquake and also the effects of wind pressure on the building, while the shingle itself provides an excellent damp-course The additional cost ranges from 1½ per cent for large city buildings to 6 per cent for dwelling houses.

It may be recalled that, fifty years ago, Prof. Milne experimented with a similar foundation in Japan, and that, still earlier, lamp tables resting on spheres had been used in Japanese lighthouses by Messrs Stevenson, the well-known lighthouse engineers[1] Milne's building, 20 ft. × 14 ft., was made of wood and rested on four iron balls, 10 in. in diameter These lay on saucer-shaped iron plates fixed on the heads of piles, and similar plates attached below the building rested on the balls From the records of seismographs placed inside, it was seen that, with an earthquake, there was a slow motion of the building to and fro, but that all the sudden motion or shock was destroyed Afterwards, in order to increase the rolling friction, Milne lessened the size of the balls until each pier of the building rested on a handful of ¼ in cast-iron shot The house then stood firmly during storms of wind and, with the earthquake of February 12, 1884, it remained practically unmoved[2]. C. D.

University and Educational Intelligence

CAMBRIDGE —The Clerk Maxwell scholarship for original research in experimental physics and especially in electricity, magnetism and heat has been awarded to H Carmichael, research student of St John's College The value of the scholarship is £210 a year for three years.

THE Royal Technical College, Glasgow, after four years of decreasing student enrolments, is able to report for the past year an increase, from 878 to 910, in the number of its day students, and although there was a small further decrease in the number of evening students (to 2,485) the aggregate number of hours of attendance shows an increase, and it is hoped that the downward trend since 1929 has at last been arrested There was a marked increase in the volume of advanced work Some indication of the exceptional range and standard of the evening classes is given by the fact that 95 graduates of the Universities of Glasgow, Edinburgh, Aberdeen, St Andrews, Cambridge, London, Leeds, Sheffield, Belfast, Allahabad, Calcutta, Dacca, Madras, Rangoon and Kyoto were enrolled The *Research Journal* inaugurated by the College ten years ago has published, in all, 167 original contributions by the staff and senior students, chiefly in the fields of chemistry (48), mechanical engineering (41), natural philosophy (25), metallurgy (16), bacteriology (14) and electrical engineering (11)

Science News a Century Ago

Airy receives the Lalande Medal

The Lalande Medal of the Paris Academy of Sciences, founded in 1802 by the famous French astronomer Jerôme de Lalande (1732–1807), was for some time the blue-riband of the astronomical world. In his "Autobiography", Airy recorded that in November 1834 "the Lalande Medal was awarded to me by the French Institut, and Mr Pentland conveyed it to me in December" The following year he recorded, "On Jan 9th 1835 I was elected correspondent of the French Academy, and on Jan. 26th Mr Pentland sent me £12 6s, the balance of the proceeds of the Lalande Medal Fund"

The Gallery of Practical Science

An advertisement in the *Times* of January 9, 1835, ran as follows "Gallery of Practical Science, Adelaide-street and Lowther-arcade, Strand.—The Grand Exhibition is re-opened to the public daily, at 10 o'clock—Steam-engine and carriages travelling on a Rail-road—Clifton Suspension Bridge—Magnets of extraordinary power, producing brilliant light and electric phenomena—Steam Gun discharging 20 balls in a second—Beautiful Illustrations in Optics—Steam Boat Models moving in water—Painting—Statuary—Music and many entertaining Novelties, including a splendid Microscope Admission to the whole 1s"

Sir Felix Booth made a Baronet

On January 10, 1835, the *Mechanics' Magazine* said "His Majesty has recently conferred a baronetcy on 'Felix Booth Esq, of Roydon Hall, in the county of Essex', avowedly for his public spirited conduct in fitting out at his own expense the expedition to the Polar regions under the command of Captain Ross Sir Felix Booth served the office of sheriff of London a few years ago, but on that occasion escaped the honour of knighthood, so often inflicted on the holders of that dignity, on some such important occasion as the bringing up of a loyal address It is believed that the present is the first instance of a civic baronetcy having been bestowed for services in the cause of science Captain Ross has also been knighted and received permission to wear the insignia of his numerous foreign orders in England " Sir Felix Booth was born in 1775 and died in 1850 Boothia Felix was named after him by Capt. Ross.

American Ice sent to India

In 1834, the American sailing ship *Tuscany* carried a cargo of ice from North America to India, and on January 10, 1835, the *Mechanics' Magazine* recorded that the master of the vessel had been presented with a handsome silver vase bearing the inscription: "Presented by Lord William Bentinck, governor-general and commander-in-chief of India, to Mr Rogers, of Boston, in acknowledgement of the spirit and enterprise which projected and successfully executed the first attempt to import a cargo of American ice into Calcutta " About 100 tons of ice was conveyed in the *Tuscany* The selling price was 6¼ cents per lb. and it was calculated that "the owners received 12,500 dollars upon an investment which including the cost of all the extra precautions for preserving the ice, did not exceed 500 dollars".

CONTENTS

Co-ordinating Agricultural Research

ORGANISED agricultural research in Great Britain is developing along lines similar to a modern industry The chief research centres confine their activities to one or a few aspects of agriculture, and in this respect may be compared to factory shops, in each of which the operatives concentrate on some particular stage of production and usually know little of the processes carried out in other shops This highly specialised type of organisation is one of the most economical that has yet been devised, but its success depends largely on the existence of a central executive body, capable of ensuring the closest co-operation and co-ordination between the different departments In recent years, the need for an analogous executive body to co-ordinate agricultural research in Great Britain has become increasingly apparent and has been accentuated by the present tendency to regard agricultural development as one of the most important parts of national policy When Government not only subsidises agricultural research but also determines agricultural policy, its obvious duty is to see that the money spent on research is used to the best advantage for the furtherance of its policy

In the other fields of applied science subsidised by national funds, co-ordination has for some time been effected through the Medical Research Council and the Council for Scientific and Industrial Research In 1931, the framework of the scheme for the national supervision of subsidised research was completed by the establishment, by Royal Charter, of the Agricultural Research Council, which has just issued its first annual report*

The chief duty of the Agricultural Research Council is to give advice on research to the agricultural departments and to the Development Commission, and to make recommendations with regard to the administration of the subsidies granted by the Treasury, amounting in 1931 to about £390,000 The Council works in close collaboration with the Medical Research Council and the Council for Scientific and Industrial Research, each of which must have at least one member on the Agricultural Research Council The work of the latter, however, is complicated by the fact that, when it came into existence, there was already an extensive agricultural research organisation

* Committee of the Privy Council for the Organisation and Development of Agricultural Research Report of the Agricultural Research Council for the Period July 1931—30th September 1933. (Cmd 4718) Pp 205 (London H M Stationery Office, 1934) 3s net

operating under the Development Commission and the Agricultural Departments of England and Scotland. It is faced with the delicate task of adapting this organisation, initiated in 1911, to the economic and political conditions of the present time

A danger which the research worker may foresee in the creation of a co-ordinating body controlled by Government is that political influences may be introduced into the direction of agricultural research The Council's report should allay all fears on this score, at least for the immediate future It has been written not only with exceptionally broad vision and a true appreciation of the present needs of agricultural research, but also in a most interesting and informative style

In the period covered by the report, the Council's main achievement has been to make a general review of British agricultural research This has involved more than a hundred meetings of committees and sub-committees, and frequent visits to twenty-two different research institutes In its future difficult task of co-ordination, which will demand the willing co-operation of all concerned, the first annual report will be of the utmost value not only to the Council but also to the directing bodies of institutes which may be called upon to modify their research programmes to fit the general scheme. The whole report forms a permanent and authoritative record of the progress and achievements of agricultural science up to 1933, and it illustrates in an exceptionally lucid manner the interconnexion of the different branches to form a single science

Every section of the report appears to have been adequately treated, although more prominence is given to veterinary research than to any other subject, and eight special committees have been formed to advise on the study of the chief animal diseases This, however, is in accordance with the policy of the Council to adapt the national research programme to the probable needs of agriculture in the immediate future The Council foresees a large increase in Britain's animal population as a result of recent legislation, and recommends that science should, so far as possible, forearm the farmer to cope with the inevitable spread of diseases —an essentially practical outlook which may arouse mild criticism from non-veterinarians who still believe that the discovery of a truth is of greater significance than its economic value But agricultural research workers, though they may regret the gradual encroachment of bureaucracy on the freedom of scientific investigation, have to recognise that they are primarily public servants whose first duty is to perform their allotted tasks in the social machine A slight loss of freedom is compensated by a greater sense of security in what is now formally acknowledged as a profession

The establishment of a national research council marks the beginning of a new epoch in the history of British agricultural science, and so long as the Council interprets its functions in the manner indicated in its first report, both research workers and institutes are assured of the fullest consideration compatible with a planned organisation

Reviews

Population Prospects in the United States

Dynamics of Population. Social and Biological Significance of Changing Birth Rates in the United States By Frank Lorimer and Frederick Osborn Pp. xiii+461 (New York The Macmillan Co, 1934) 15s net

THIS book consists of four parts, the first of which, entitled "Population Trends of American Groups", discusses, in four chapters, first the trend of the national population, and then the three aspects of differential fertility, represented by the contrast between town and country, by racial differentiation, and by differences of social class. The writers realise that population growth in the United States will slow down, cease and change to population decline in the absence of any abrupt change in the trend of the birth-rate, or in the possibility of attracting immigrants They express a somewhat ostentatious indifference to the economic effects of this population tendency, which has already doomed the economic prospects of thousands of once hopeful small communities, and has forced the Federal authorities to consider a policy of deliberate depopulation of part of the vast area brought under cultivation by the enterprise of American farmers The authors state truly that the theory of optimum population is at present still in the stage of preliminary definition and clarification, and add, somewhat vaguely, "It may be that a higher standard of living for individuals could be maintained in this country with a population very much greater or very much less than 150 million," without reference to the fact that personal hopes, enterprise and investment, in addition to municipal, State and Federal policy,

have in the past all been dominated and directed by the confident expectation that the resources of their territory were destined progressively to be more and more fully utilised

On the other hand, the authors believe, and later produce ample evidence for their view, that the "large differentials in reproduction rates among population groups" in their country need far more critical attention than they have yet received, and determine to devote the rest of the book to the study of changes taking place within this population This is not, avowedly, to be taken to mean that the authors consider eugenics more important than economics, but that they recognise that population changes may affect the composition and standards of a people, wholly apart from any changes in their genetic qualities "Children tend to be like their parents in part because they are usually brought up in an environment similar to that which has shaped their parents It is evident, therefore, that the differential increase or decrease of groups with varying social heritage may affect the proportion of different culture levels in our population, just as the differential increase or decrease of groups with varying biological heritage may affect hereditary capacities The study of both factors is important "

In the following chapter the authors demonstrate that, as in other countries, "there is at the present time a tremendous rural-urban differential in reproductive tendency," and quote Thompson and Whelpton on the current situation "If prosperity again permits a resumption of the movement of the surplus farm population to city jobs the present urban exodus may do little permanent harm If this should not occur, there is a danger of developing a large poverty-stricken population on the millions of acres of land which is submarginal for business farming, but which will permit self-sustaining farming on a low standard of living "

The authors consider "It is impossible to determine exactly, at the present time, the relative reproduction trends of whites and negroes in the United States", but evidently think there is no great difference They point to unusually high fertility for several minor racial groups, namely Mexican, Japanese, Chinese and American Indians They feel also that "there is little interest in the reproduction rates of foreign groups during the first generation of American residence, from the long range standpoint, because foreign groups become native groups in the second generation"

The longest chapter in this part is naturally devoted to the large differences in fertility between social groups, classified by occupation or by economic status. They find that these differences in fertility among urban social classes have remained fairly constant during the last fifty years, although the absolute rates for all classes have declined considerably during this period They add, however, "It seems very likely that differentials in fertility among social groups in the United States may become somewhat narrower in the course of the next fifty years " This anticipation seems not to be based on any American data, but on the somewhat credulous acceptance of recent not very well substantiated statements concerning several European cities, as to the validity of which it would be but prudent to reserve judgment

The methods and attitude of the authors have been illustrated above from the first of the four parts into which the book is divided Part II deals with the "Measurable Characteristics of American Groups", using, as before, regional racial and social sub-divisions Part III is devoted to the 'Influence of Differential Reproduction on the Characteristics of the American People" under the two headings of its social significance and its biological significance , while Part IV discusses the causes and control of population trends Causes are divided into physical and medical factors on one hand, and the economic and social factors on the other Under the possibilities of social control are discussed numerous current movements of thought and political action, which may be believed, with more or less reason, to affect the situation

In spite of the enormous field which the book is thus designed to cover, it does not suffer from compression, but more frequently from prolixity and occasionally from repetition The laudable aim of restricting the conclusions to those which can be based on ascertained facts has, of course greatly limited the field to be traversed As all who are familiar with the subject know, the material available for discussion would be still more greatly restricted had the authors required not merely that some objective data should be available, but also that it should be sufficient to warrant statistically valid conclusions It is a sound canon of science that, when they are available, well authenticated, and free from contradictions, direct observations must be preferred to all indirect inferences from other facts It is, however, a serious and rather widespread failing, particularly dangerous in the social sciences, to give such preference to findings based on data, while their consistency, accuracy, or relevance are open to serious question In any discussion of social causation we may find some ascertained facts of compelling authority, others which should not be neglected, and others which are entirely irrelevant Workers in the social sciences should remember that discussions of causation, even in the most exact sciences, invariably turn on the validity of

some rationally connected system of hypotheses, and never wholly on direct observations. It is, naturally, in the latter parts of this book that the lack of a theoretical background, such as the economists have possessed for more than a century, is most severely felt This criticism should not be taken as denying to the authors a great measure of success in an immensely arduous undertaking

R A FISHER

The Endocrine Principles

Recent Advances in Endocrinology By Prof A T Cameron Pp vii+365 (London J and A Churchill, 1933) 15s

THE endocrine principles are of interest from three aspects, clinical, chemical and social, for there is often an attempt to ascribe differences of personality to their variations Recently it is on the chemical side that most progress has been made, many of the principles having been isolated in pure crystalline form and even synthesised, so that it is possible to make the physiological study of the mechanism of their action with material of definite composition and structure There is progress too on the clinical side, though these aspects are more a matter of controversy. Internal secretions are produced by the thyroid, parathyroid, pituitary and adrenal glands, by the islet tissues of the pancreas, the mucous membrane of the intestine and the organs of reproduction From these there has been isolated thyroxine, adrenaline, insulin and œstrin in crystalline form, and there is presumptive evidence for other compounds

Prof Cameron gives six chapters to the well-established endocrine principles and one to the more presumptive ones, and devotes a final chapter to their interrelationships He summarises what is known regarding their chemistry, their method of action, their physiology and their clinical behaviour. The book has an appeal, therefore, to the medical, as well as to the biochemical, expert. Each chapter has rather full references to the literature up to the end of 1932 and is appropriately illustrated.

Now that the structure of these compounds is known, it should be noted that they bear no relation to one another, and it becomes important to ascertain some clue as to their utility in metabolism This is still largely guesswork, but there seems to be a hint of some general relation to oxidation phenomena

The thyroid principle, for example, according to Plummer, exerts an influence on the oxidation proceeding in all the cells of the body and thus produces its actions · the behaviour suggests control of specific reactions. Insulin brings about the disappearance of glucose from the blood : it is undecided whether it facilitates glycogen formation or direct oxidation of glucose. Adrenaline likewise has an effect on the interconversion of glycogen and glucose Of the less-known endocrines, secretin is the most interesting · it appears, like insulin, to be a protein, and acts to stimulate the outflow of pancreatic juice and bile Mellanby considers that it is carried with the bile salts to the general circulation

The author devotes a final short chapter to endocrine interrelationships, particularly those of the pituitary, which through one or other of the several principles it secretes controls (1) the thyroid and therefore the oxidative processes, (2) the adrenal cortex and thereby muscular contractility (3) the development of the gonads and hence the secondary sex organs and secondary sex characters, (4) fat metabolism to some degree, (5) the water exchanges of the body

No additional words are required to emphasise the interest of the conception that crystallisable chemical substances of relatively simple composition are able to control so many effects in the organism, and it is easy to see the many ways in which slight variations in their production can be reflected. Further deductions from these facts soon take us outside the region of ascertained scientific facts and they are wisely eschewed by the author

When a selection has to be made from so large a quantity of material, it would not be difficult to find faults of omission or over-emphasis, but it would be unfair to criticise the author for these when so much has been achieved in bringing a difficult subject into focus for detailed study Prof Cameron's book will be of definite help to all interested in this field

A New Atomic Model

The Sub-Atoms . an Interpretation of Spectra in conformity with the Principles of Mechanics By William Mayo Venable Pp viii+148. (Baltimore, Md The Williams and Wilkins Co . London · Baillière, Tindall and Cox, 1933) 9s

THIS book describes an attempt to explain spectroscopic phenomena in terms of a model of the atom conforming to Newtonian mechanics. The author assumes the existence of 'sub-atoms', each of which consists of an ellipsoidal or similarly shaped mass of positive electricity, of charge e, on which rests a smaller negative electron (charge, $-e$). The linear dimensions of the sub-atoms are inversely as their masses, and the atom of any element consists of that particular stable association of sub-atoms which will explain simultaneously its mass, atomic volume and spectrum. For the

lightest eight elements these considerations give a unique structure, but more work is required on the heavier atoms.

The production of spectra is most simply illustrated by the lightest sub-atom, which is identical with the atom of hydrogen If the electron is disturbed by an external stimulus it bounces, like an india-rubber ball on the earth, with a frequency which varies continuously as the amplitude decreases This is accompanied by the radiation of a continuous spectrum, the limiting frequency (for zero amplitude) of which is the Rydberg constant, R Similar bouncing of an electron in a molecule formed of two such atoms in line gives a continuous spectrum with limiting frequency, $R/2^2$, and the 'difference-frequency' between these two limiting frequencies gives the first line of the Lyman series Co-operation of more complicated molecules yields the other lines of the hydrogen spectrum By assuming equilibrium positions of the electron at different distances from the centre of the non-spherical positive mass, the characteristics of the secondary spectrum are similarly described in terms of difference-frequencies The theory is extended to explain the spectra of the other light elements as well as X-ray spectra, and a few remarks on certain cosmic problems are added

The author shows great ingenuity in interpreting the details of spectra, which he has taken the trouble to understand beforehand, and his idea is not to be ranked with certain fantastic alternatives to the quantum theory which have been suggested without knowledge of experimental facts It cannot, however, be considered—at least in its present form—as a serious rival to the current interpretation of spectra It follows facts throughout, often at a considerable distance, and it appears to be devoid of suggestions for increasing our knowledge. Moreover, there are many facts (for example, the existence and spectrum characteristics of isotopes), well accounted for by the quantum theory, with which it is not obviously able to deal at all

These defects would be considerably discounted if the theory were, as it claims to be, based entirely on Newtonian mechanics, but the behaviour of the atoms and molecules in producing spectra by no means follows inevitably when Newtonian laws are applied to the assumed structures In the last resort the theory requires postulates as arbitrary as those of the quantum theory, so that a satisfactory comparison can be made only on heuristic grounds, where it is not likely to survive The author is, nevertheless, to be commended for having produced a very interesting and suggestive hypothesis and for his diligence in developing it so far as he has done.

Science and Poetry

The Poetical Works of Kenneth Knight Hallowes Vol. 1. *1896–1934* Pp xvi+212+2 plates. (London. Methuen and Co, Ltd, 1934) 7*s* 6*d*. net

MR HALLOWES in his recent book has raised again an oft-discussed question and given some interesting illustrations of its possible solution The question is how far can poetry express and keep pace with the discoveries of science The illustrations are drawn from poems of Mr Hallowes himself, when on the Geological Survey of India in the years 1905–23 In speaking of these, it will be sufficient here to point out that Mr Hallowes has at least three of the essentials for carrying out the work to which he rightly attaches high importance He has an observant eye, a passionate love of Nature and a profound sense of one of the greatest truths which modern science has revealed, namely, that the earth and all that it contains are subject to incessant change, and that what we see, though the result of these changes, is often to the superficial glance quite different It is due to this apparently paradoxical transformation that Mr Hallowes owes some of his most telling word-pictures, for example, "From rock once molten fire blue speedwells bloom" Such pictures of transformation are, as we might expect, frequent in the work of a man who from the starting point of geology sets out on the work of a poet of science

How does science fare generally in the works of poets? Our contemporary bards tend to deal, in short and rather emotional fragments, with the psychology of persons or striking events. Such psychology is by no means scientific If we look at the older poets of rather larger scope, we find that the ideas of the Greek philosophers, who were also the men of science, were quite naturally expressed in verse There was no such barrier in modes of expression as have since arisen Then, with the Romans, we have the immortal poem of Lucretius, which actually puts into verse a great scientific hypothesis In the Middle Ages, Dante gives us in more poignantly human form the science and philosophy of his day. Among the moderns, it is noticeable that Goethe, the greatest poetic force of the nineteenth century, was also an important figure in the science of those times Wordsworth, Browning, Tennyson, Sellby Prudhomme, Alfred Noyes have all written poetry inspired by science One would be inclined to say that the general lack, of which Mr Hallowes speaks, is rather due to the dispersive, uncontrolled and rather aimless character of much of the writing and thinking of the present day than to any long-standing divorce between poetry and science.

Short Notices

Contribution à l'étude du peuplement zoologique et botanique des îles du Pacifique. Par L Berland, J. Berlioz, E. H Bryan, Miss E Cheesman, L Joleaud, L. Chopard, L Germain, A Guillaumin, K Holdhaus, E P Mumford, A M. Adamson, P Rivet, L. Seurat, C Skottsberg, E Topsent, C Vallaux. (Société de Biogéographie, 4) Pp iv+288 (Paris Paul Lechevalier et fils, 1934) 70 francs

THE volume consists of sixteen papers by specialists who deal with particular parts of the subject Two papers are geographical or geological, three are botanical, the remainder deal mainly with zoology, four of them with insects One must recognise that it is extremely difficult to cover the ground adequately, for there are parts of Oceania and certain groups among the plants and animals about which we possess no information at all But there are several important topics to which less than justice is done There is, for example, almost nothing about the butterflies—a very important group to the student of island faunas, for these insects have been carefully collected, and a connected account of them could have been written The birds also furnish an abundance of material, but the paper which deals with them is most indefinite, with facts about the birds of New Zealand and the Hawaiian Islands, but next to nothing on the avifauna of such well-known groups as Fiji and Samoa Attention must be directed to one error in fact it is stated that crocodiles occur in the Tuamotu islands, but actually their eastward limit is in the Santa Cruz, more than 3,000 miles to the west The error is important, for one of the authors, having extended the range of crocodiles across Polynesia, is inclined to regard them as evidence that the area has a 'continental' fauna

The critic must not forget, however, that, in the present state of knowledge, a work of this nature must inevitably be fragmentary Certain parts of it are excellent, for example, the general description of the distribution of insects by Holdhaus and the more specialised articles on Orthoptera and on Arachnida by Chopard and Berland The value of the book as an introduction to the subject would have been greater had more attention been given to completing the lists of references, and had special and general indexes been provided P A B

The Chemical Formulary. a Condensed Collection of Valuable, Timely, Practical Formulæ for making Thousands of Products in all Fields of Industry. Editor-in Chief, H Bennett Vol 1. Pp x+595 (Brooklyn, N Y The Chemical Formulary Co.; London H K Lewis and Co, Ltd, 1934) 6 dollars; 27*s*. net

IT is difficult to assess the value of a book of this kind until one has lived with it for years. Only then can one discover whether any process of trial or selection has led to the inclusion or exclusion of material, or whether—as appears to be the case in this instance—there is no kind of entrance examination prior to admission to its pages. The result is that we have a book containing a very large number of formulæ, some attractive in their simplicity ("Liquid brilliantine light mineral oil, perfume"), some intriguing in their application (such as artificial butter), and others—very many others—which involve the use of materials of undescribed (and hence presumably unknown) composition appearing under proprietary names It is true, however, that the book is accompanied by a folder quoting many such names, and stating the suppliers of the preparations

The great variety of recipes is classified in sections, but within the sections similar entries are not always in juxtaposition Some of the recipes are stated to be in use commercially, whilst others have been taken from patent specifications and the literature, sources which, the reader is reminded, are often subject to various errors and omissions In view of this fact and of the fact that the significance and application of a great many of the formulæ are intelligible only to those having specific technical knowledge, the ordinary person will not find that the book obviates any need for technical assistance.

Electron Tubes in Industry By Keith Henney Pp ix+490 (New York and London McGraw-Hill Book Co, Inc, 1934) 30*s* net

IN recent years great advances have been made in the use of electronic devices in industries outside the sphere of 'communications' Mr Henney's book should do much to further the advance The author, who deals with the varied and sometimes little appreciated applications of electron tubes, is closely connected with many sides of the world of electronics, and this book should find a place on the shelf of every industrial engineer

The first two chapters deal with electron tube theory and circuit application, and are sufficient to enable the engineer not familiar with these tubes to understand intelligently the various circuits employed The remaining chapters are devoted to the vacuum thermionic valve, the gas-filled tube, and to light-sensitive devices; the various industrial and laboratory applications given being chosen to demonstrate the fundamental principles involved The respective merits of the different tubes available are discussed both from theoretical and practical points of view, and the newer forms of tubes, such as the gas-filled relay, also have their place. An excellent bibliography completes each section

Isolated examples from the book will indicate the wide field covered; the use of the vacuum tube amplifier and photo-electric cell for automatic temperature control, the use of the grid-controlled gas tube as an inverter and commutator; these will be of particular interest to engineers, while physicists will also find the book of value, for many applications of the tubes, particularly in precision measurements, will make an especial appeal to them. M. B

Elektrische Gasentladungen ihre Physik und Technik Von A v. Engel and M Steenbeck Band 1 *Grundgesetze* Pp vii+248 25.50 gold marks Band 2 · *Entladungseigenschaften, Technische Anwendungen.* Pp. viii+352. (Berlin Julius Springer, 1932, 1934) 33 50 gold marks

THE first volume of this monograph gives an excellent and condensed account of the methods by which ions are generated and destroyed, and of the laws which govern their passage through a gas In the first part of the second volume the various forms assumed by the electrical discharge through gases are discussed, and so far as possible explained in terms of the conclusions reached in the first volume The treatment is intended as a necessary basis for the understanding of the conduction of electricity through gases, and does not pretend to be complete

The absence of any historical or critical survey is apt, perhaps, to encourage in the reader the feeling that a great deal more is known of the details of some of these processes than is actually the case, and that the explanations given and the data furnished are, in fact, correct. On the other hand, it is extremely easy to find the information which the practical worker in the field requires, and the clear graphs and tables render unnecessary those searches for data in the original papers which are so tedious and often so unsatisfactory This part of the monograph should prove valuable to those who must design or use apparatus employing gaseous discharge phenomena in the laboratory or in technical work

The second part of the second volume is too limited in scope to be of much value It describes various technical applications of the discharge through gases, but in far too superficial a manner For example, a reader who wished to use a Geiger counter would obtain little practical information from the description given M E O

Mathematical Problems of Radiative Equilibrium By Prof Eberhard Hopf (Cambridge Tracts in Mathematics and Mathematical Physics, No 31) Pp viii+105 (Cambridge · At the University Press, 1934) 6*s*. net

THIS tract is an authoritative exposition of problems of radiative equilibrium by one of the original workers in the subject. An initial chapter gives a summary of the general theory and main problem to be treated, namely, the determination of the radiation field of a star when the coefficients of absorption and scattering, the emissivity and the law of scattering are given The method is based on the solutions of certain integral equations and is expounded in detail in the succeeding chapters, which deal in turn with the cases of purely absorbing and grey material in local radiative equilibrium (Schwarzschild-Milne model) and that of monochromatic radiative equilibrium with scattering but zero emissivity (Schuster-Schwarzschild model) On account of the rigorous analytical method employed, the book is one for the specialist rather than the general reader, and will prove a very useful guide for those interested in the subject.

An Introduction to Logic and Scientific Method By Morris R Cohen and Ernest Nagel Pp xii+467 (London George Routledge and Sons, Ltd , 1934) 15*s* net

THIS book, by two American teachers of philosophy, helps to show how far the best representatives of logic in modern universities have travelled from the Aristotelian tradition which formerly prevailed. In an earlier generation Mill and Stanley Jevons, and later Neville Keynes, did much for the reshaping of the old formal logic, and for the development of an inductive logic which brought the subject into more vital relation with the methods of scientific investigation In more recent times, logical theory has made progress in different directions, so that for educational purposes an eclectic treatment of the whole subject is desirable Such a treatment is accomplished in this admirable book

The authors have, we think wisely, adopted a fairly conservative attitude towards the traditional views, with which they have sought to connect the newer work in exact logic In giving the main results of symbolic or mathematical logic, they have refrained from stepping across the boundaries between logic and mathematics They hold that the alternative systems of logic which have been worked out are really different systems of notation for the same logical facts Their illustrations, freely drawn from the natural sciences, are such as a college student may be expected to understand and appreciate We think highly of the attempt of the authors to provide a sound introduction to the principles of logic and scientific method

Recent Advances in Vaccine and Serum Therapy By Prof A Fleming and Dr G F Petrie (Recent Advances Series) Pp x+463 (London . J and A Churchill, 1934) 15*s*

AN authoritative and up-to-date account of modern serological remedies and therapeutic and preventive vaccines is much needed by the medical practitioner, and this book should go far to supply this want Dr. Petrie deals with the serological side, including the treatment of snake, scorpion and spider bites, and Prof Fleming with the vaccines, including non-specific vaccine and protein therapy. The veterinary side of the subject is also considered by both authors.

Though primarily concerned with recent advances, the older work is referred to, and the volume, which is well produced and very readable, provides a comprehensive practical account of the whole subject A chapter is devoted to bacterial variation in relation to immunising power, and the importance of the 'rough' and 'smooth and 'H' and 'O' variants is detailed, and the work of Perry, Findlay and Bensted on the suitable strain of typhoid bacillus for the preparation of anti-typhoid vaccine is included. A lengthy chapter is devoted to the vaccine treatment of chronic rheumatic conditions, in the preparation of which Prof. Fleming is able to draw upon his own considerable experience.

A short bibliography is appended to each subject, and an index of authors as well as of subjects is included.

Arctic Meteorology*

By DR G C SIMPSON, C B , C B E , F R S

IN 1905 appeared Mohn's discussion of the meteorological records obtained during Nansen's drift across the north polar basin on board the *Fram* during the three years October 1893–August 1896 No one who is interested in polar meteorology needs to be reminded of the outstanding value of that great work, which has been for thirty years the source of practically all we know about the atmosphere over the Arctic Ocean

Now has appeared another great contribution to our knowledge of arctic meteorology, again obtained on the drift of a Norwegian ship and discussed by another outstanding Norwegian man of science When Mohn's work appeared, the name *Fram* was a household word to the whole civilised world , but how many people even in England know anything about the *Maud* ? Yet the *Maud's* sojourn in the Arctic, where she was engaged on the same enterprise of scientific research, was even longer than that of the *Fram*, and her scientific results no less valuable

Amundsen's successful dash to the South Pole was a mere episode in a project on which he had been working for several years : namely, to repeat Nansen's drift across the Arctic Ocean in the *Fram* In fact, he was on his way from Norway to the Bering Straits around Cape Horn when he changed his plans at Madeira and went to the Antarctic On his return to Norway he proceeded with his original plans ; but the old *Fram* was found to be nearing the end of a glorious life and was no longer fitted for such strenuous work Then the War broke out, but Amundsen did not relinquish his plans In 1916 he gave orders for a new ship to be built, on the lines of the *Fram*, but smaller ; on June 7, 1917, the new ship was launched and christened *Maud*

On July 18, 1918, the *Maud* left Vardø, with Amundsen in charge, the total ship's party being only nine men. The plan was to sail eastwards along the Siberian coast towards the Bering Straits and then turn northwards into the ice and drift with the pack across the Pole. That was the plan, but it did not eventuate . for seven years the *Maud* remained in the Arctic the greater part of the time, either frozen fast near the coast or drifting aimlessly to the east of the New Siberian Islands.

Luckily for him, and more so for science, Amundsen in 1917 invited H. U. Sverdrup, a young Norwegian who had never been in the Arctic before, to take charge of the scientific work of his expedition Sverdrup consented and was one of the two men who alone saw the expedition through, starting with the *Maud* at Vardø in 1918 and leaving her when she returned to Nome in August 1925

During the first three years, Sverdrup was the only trained scientific worker on board—Amundsen helped with the magnetic work but he was disabled for a long period with a broken arm—but in 1922 F Malmgren, whose tragic death after the disaster to Nobile's airship in 1928 will be fresh in the memory of most, joined the expedition as assistant scientist In these circumstances the amount of scientific work carried out on the expedition is amazing Observations of the first importance on oceanography, terrestrial magnetism, atmosphere electricity and meteorology were carried out , zoological, botanical and geological collections were made, and Sverdrup spent seven and a half months living with a little-known group of native nomads in order to study their language and customs, and characteristically enough during the whole time he was with them he made meteorological and magnetic observations

The volume on meteorology which has just been published consists of two parts : Part II (527 pages) contains all the data in 28 well-arranged tables, and Part I is a discussion running to 331 pages written by Sverdrup himself Naturally one compares Sverdrup's discussion of the results of the *Maud* expedition with Mohn's discussion of the *Fram* results There is one striking difference Mohn's discussion is limited almost entirely to working up the statistics of the observations, while the outstanding feature of Sverdrup's treatment is his investigation of the physics and dynamics underlying the observations. The difference is symptomatic of the great advance made by meteorology in the interval Thirty years ago meteorological observations, even in settled countries, consisted of little more than observations of pressure, wind, temperature, cloud and precipitation all made at the surface, and the meteorologist could do little more than find statistical relationships between them Such were the observations carried out on the *Fram*, and Mohn's discussion was necessarily statistical. On the *Maud* similar observations were made, and Sverdrup has treated them in the same way and quite as thoroughly as Mohn treated the *Fram* results ; so that the two sources of information

* The Norwegian North Polar Expedition with the *Maud*, 1918-1925 Scientific Results. Vol II Meteorology. By H U Sverdrup. (Geofysisk Institutt, Bergen, in co-operation with other Institutions)

support and supplement one another In the *Maud*, however, many other observations were made, and it is Sverdrup's complete and able discussion of the light which these new observations throw on old meteorological problems which makes his discussion so interesting and valuable

For the first time we have a mass of observations from the upper air in the Arctic obtained by sounding balloons, pilot balloons and kites The observations of the upper air temperature made by balloons and kites, of which there were 162 ascents, reveal an unexpected and important distribution of temperature over the ice The few previous measurements of upper air temperature made over ice in polar regions had led us to expect a marked temperature inversion near the snow-covered ground during the winter In other words, that there was a 'cold layer' of air near the surface.

It was supposed that this layer was easily removed by the wind The observations made on the *Maud* show, however, that this is not the case All that the wind does is to stir up the layers quite near to the ground In this stirred-up layer, as one would expect, temperature decreases with height, but above it the strong inversion remains and the normal fall of temperature with height does not set in, in any season, much below 1,000 metres There are, therefore, three definite layers of air over the Arctic sea ice, (*a*) a layer, 150 m. thick in the winter, increasing to 500 m. thick in the summer, in which the temperature decreases slightly with height, (*b*) a layer in which there is a strong inversion, the top of which varies in height above the surface from 280 m in the winter to 600 m in the summer, (*c*) a layer probably reaching to the tropopause in which the temperature decreases with height in the normal way. The pilot balloon observations, of which there were 621, gave very complete information regarding the variation of wind velocity and wind direction with height.

The peculiar distribution of temperature and the observed variations of wind with height over the ice can only be caused by eddy motion set up in the lower layers of the air, and Sverdrup uses the results of his observations to test the various formulæ put forward by Richardson, Schmidt, Köhler and Hesselberg in their theoretical work on the eddies in the atmosphere. Sverdrup's discussion is a valuable contribution to a difficult subject, and the numerical values he obtains will be found of use in a number of problems

The diurnal variation of temperature in polar regions has been the subject of much discussion since the writer pointed out in his discussion of the meteorological observations made on Capt. Scott's Antarctic expedition that there are two types of daily variation, in one of which the maximum amplitude occurs in a spring month and in the other in a summer month The observations taken on the *Fram* showed a rapid increase in the amplitude after the return of the sun until April, after which it decreased to very low values in the summer months, while in McMurdo Sound the amplitude increased steadily from the appearance of the sun until the summer and then decreased again as the altitude of the sun decreased The observations on the *Maud* showed the same type as observed on the *Fram*, and Sverdrup gives a new explanation It has already been mentioned that the lowest layer of the atmosphere in which the eddies cause the temperature to decrease with height thickens from the winter to the summer Sverdrup considers that the layer is warmed up by contact with the ground and, therefore, as it gets thicker it takes more and more heat from the surface After the sun returns, the daily temperature range tends to increase as the altitude of the sun increases, but the thickness of the layer also increases and that tends to reduce the range. The actual course is due to the relative efficacy of the two factors, the solar effect being the stronger until about April and then the eddy effect predominates

During the last three years, after Malmgren had joined the expedition, an increased number of observations became possible, and amongst these were measurements of the incoming solar radiation, the long wave radiation received from the sky, the temperature of the actual surface of the snow and the temperature of the ice at three depths below the surface These data supply all the information necessary to calculate the flow of heat during calm weather to and from the surface, and one of the most interesting chapters in Sverdrup's discussion is that in which he uses the results of these observations to investigate the heat balance of the atmosphere over ice-covered surfaces He calculates that the average minimum temperature on clear calm days in the winter should be $-38 \cdot 8°$ C.; the observations give $-38 \cdot 9°$ C. According to the calculations, the absolute minimum temperature over the frozen polar sea should lie between $-43 \cdot 9°$ C and $-49 \cdot 5°$ C.; the actual observations taken on the *Maud* in four winters give values varying between $-41 \cdot 7°$ C and $-46 \cdot 3°$ C. The lowest possible winter temperature at Arctic land stations is calculated to be between $-63°$ C. and $-75°$ C, the former being the more probable, the lowest recorded temperature is $-69 \cdot 8°$ C at Werchojansk in February 1892. By using the value of the 'eddy diffusivity' found from the kite and

balloon observations, similar calculations are extended to conditions during the summer and in winds This discussion of the heat balance is of particular value for a large number of meteorological problems

During the latter part of the expedition, entirely new methods of observing amounts of precipitation and the formation of hoar frost were devised and successfully used, but lack of space forbids further reference to the fascinating results obtained This short article must be closed by a reference to the last chapter in the work, entitled "The Circulation of the Air" For the first time the new ideas of the Bergen school of meteorologists have been applied to the interior of the polar regions Depressions with their characteristic 'fronts' are recognised and their motion determined in so far as that is possible without synoptic charts There appear to be two main permanent 'fronts' in the Arctic on which depressions form in the winter months—one in north-west Siberia, near to the Bering Straits, and the other between Spitsbergen and Norway During the winter months the pressure distribution over the Arctic is found to be mainly anticyclonic, but the anticyclonic conditions are frequently destroyed by deep cyclones which form on these two fronts and progress eastwards and northwards into the centre of the polar basin In the summer the general weather situation is of a more cyclonic character, but the actual disturbances are small and weak compared with the deep winter cyclones

Development of the Modern Broadcast Receiving Valve

THE specification of most modern broadcasting receivers contains an imposing list of titles describing the various thermionic valves employed in the set The simple terms, 'high-frequency amplifying', 'detector' and 'low-frequency amplifying', are now no longer sufficient to describe the type of valve and its function in a wireless receiver, and one is led to speculate whether those investigators who were responsible for the introduction of the terms 'diode' and 'triode,' about sixteen years ago, envisaged the possibility of the octode as a manufacturing proposition in 1934 In the presence of such attainments, it is useful to review the developments which have led to such a complicated valve Such a review, with special reference to the technique of the manufacture of receiving valves on a mass-production basis, was made by Mr S R Mullard in his chairman's address to the Wireless Section of the Institution of Electrical Engineers on November 7 last

The thermionic valve, in both the two- and three-electrode forms, was in existence prior to 1914, and its early development was considerably accelerated by the demands of wireless communication during the War period After this period, the main receiving valve available in Great Britain was the then well-known *R* type, comprising a cylindrical anode, spiral grid and a co-axial filament of pure tungsten. This valve was available for general purposes as a high- and low-frequency amplifier, a detector or as an oscillation generator Judged by present-day standards, the valve was very inefficient and, incidentally, rather expensive. Its chief extravagance, as a valve to be used almost universally with batteries, was its filament, the function of which was to produce an electron emission of one or two milliamperes The main improvements in this direction were the introduction in turn of the thoriated tungsten filament and the oxide-coated filament, which is in use in most modern receiving valves, the more recent development of the mains-operated valve has involved the necessity for electrically insulating the heater from the metal cathode carrying the oxide coating The use of a heated wire coated with oxides of one or more alkaline earths, such as barium and strontium, is reminiscent of the early work on thermionic emission carried out by Elster and Geitel about fifty years ago

Having placed the cathode in a fairly satisfactory position as an efficient source of electron emission, the valve designer has had to turn his attention to the provision of more than one grid and one anode in order to meet the requirements in the progress of receiving circuit technique. By means of lantern slides, Mr Mullard illustrated the constructional development of the valve up to the octode of quite recent production The desirability of keeping the overall size of the receiving valve approximately constant has necessitated the attainment of considerable precision in the dimensions and spacings of the electrode system, and the valve has therefore become, very largely, a machine-made article

The purpose of the introduction of the additional electrodes into the triode, and the functions fulfilled by the various types of modern receiving valves, are usefully described by A. L M Sowerby in a series of four articles in recent numbers of the *Wireless World* (September 21 and 28, October 12 and November 2) In the first place, the attainable amplification from a three-electrode valve, when used at radio frequencies, is limited by the coupling between the input and output circuits effected through the capacitance between the grid and anode This difficulty was overcome by the intro-

duction of a screen-grid between these electrodes, and the tetrode is thus available as an efficient high-frequency amplifier It is also desirable to be able to vary the amplification of a stage without incurring the risk of distortion of the received signals, or of decreasing the effective selectivity This is conveniently carried out by making the control grid spiral of a non-uniform pitch, so that the amplification depends on the grid bias voltage provided for the valve Here we have the tetrode with variable mutual conductance between grid and anode circuits (variable-mu tetrode)

The above types of four-electrode valve suffer a limitation in use, which is due to secondary emission effects from the anode This drawback has been removed by the introduction of a third, or suppressor, grid, which is located between the screen grid and the anode, and is in direct electrical connexion with the cathode Thus we have arrived at the high-frequency pentode, which may or may not be provided with the variable-mu characteristic The pentode is also available as an output valve specially designed to deliver audio-frequency power to the loud speaker This valve is more sensitive and more efficient than the corresponding output triode, but necessitates rather more care in design and operation with a suitable output load

Wireless receivers of the supersonic-heterodyne type require the provision of a stage in which local oscillations are generated, and of another stage in which these oscillations are suitably combined with the incoming signals to produce oscillations of the beat-frequency for subsequent amplification The oscillation-mixing process may conveniently be carried out by using a hexode valve provided with two control-grids, one for the incoming signal and one for the local oscillations, and two screen grids to separate them from each other and from the anode The introduction of a fifth grid will enable the separate triode oscillator valve to be dispensed with, and we thus have the heptode or penta-grid convertor, as a self-contained frequency-changer unit for supersonic-heterodyne reception If it is desired to be free from the disadvantages of secondary emission, mentioned above, still another suppressor grid is required next to the anode, and we have arrived at the octode An alternative arrangement of the electrodes in a frequency-changing valve, involving a triode-hexode in one envelope, was referred to in NATURE of October 13, 1934 (p 577)

The introduction of the variable-mu amplifying valve described above has enabled a system of automatic volume control to be developed, by means of which overloading of the receiver by strong signals from a local station is avoided and also the effects of fading of weaker signals from distant stations are largely counteracted These results are achieved by making the rectified signal provide the grid bias for the variable-mu valve and so control the amplification of the stage To obtain the relatively large bias voltages required, it has become necessary to use a diode as detector, further, in order to avoid loss of sensitivity in the receiver as a whole, separate detectors are desirable for the signal rectification and for the automatic volume control These detectors are provided in the double-diode valve Such a valve requires a relatively small amount of electron emission, and this may be derived from a portion of the cathode of the triode or tetrode used for audio-frequency amplification of the signals after detection Thus we have arrived at the double-diode-triode and double-diode-pentode valves used in many commercial receivers of to-day

The development of these multi-electrode valves has necessitated the use of considerable ingenuity in the design and construction of valve bases and sockets; for, except in certain high-frequency valves in which the connexion to one electrode is led out at the top of the glass envelope, all the electrode connexions are made by pins of the familiar type.

The Deutsche Physikalische Gesellschaft

IN the year 1843, Magnus was professor of natural philosophy at Berlin and created a physical colloquium, or, as the obituary notice in NATURE of June 23, 1870, says, "Graduates and undergraduates assembled round him once a week, to enjoy what he called physical conversations. Here students in turn reported on investigations recently published, the master criticising the report, and opening a discussion on those points which appeared to deserve a fuller explanation" From all accounts, Magnus was an inspiring teacher, and it was under the influence of this colloquium that, two years later, in 1845, six young physicists—Beetz, Brucke, Heintz, Karsten, Knoblauch and Emil du Bois-Reymond—founded a society which had as its object, first the communication of original papers, and secondly the issuing of an annual volume of reports on all publications of a physical nature which should have appeared during the year. The society went by the name of the *Physikalische Gesellschaft zu Berlin*, which in 1899 became the *Deutsche Physikalische Gesellschaft*, to indicate the nation-wide scope which it had attained. This Society is, then, celebrating this year, on January 14, its ninetieth birthday

Of the names of the original founders, probably

only those of du Bois-Reymond and of Beetz are familiar to the average reader nowadays, but in spite of the aristocratic indifference of some of the older representatives of science in Berlin, the Society grew rapidly. Among the fifty-three members who joined in the first year, we find the names of Dr Helmholtz, Lieut Werner Siemens and G H Wiedemann, while Kirchhoff and Clausius joined in the following year A period of wonderful fertility was beginning for German physics, and practically every name of note during that period can be found in the lists of the Society

In 1882 began the publication of the *Verhandlungen*, which, from being merely a record of meetings and short notices, later, in 1899, became a reputed journal for the printing of original papers, particularly valued for its quick publication. Meanwhile, the *Fortschritte der Physik*, published by the Society, became celebrated for the care and accuracy of its short abstracts of original papers in physics appearing in all countries The fifty years celebration held in Berlin in January 1896 under the presidency of one of the founders, du Bois-Reymond, gave evidence of the prosperity of the Society, the membership of which then numbered about three hundred The first series of photographs taken by Rontgen with his newly-discovered rays was shown, and experimental demonstrations were given by, among others, E Warburg, Arons, Aschkinass, Neesen, Rubens, Goldstein, Nichols, W Wien and F Kurlbaum—a very respectable list of names!

The new life of the Society, as the *Deutsche Physikalische Gesellschaft*, may be said to have been initiated under the influence of a discourse which Planck—a name long respected and beloved among physicists the world over—gave in December 1900 on the laws of radiation His famous paper in which the conceptions of the quantum theory were first given to the world appeared a few months later On the experimental side Goldstein and Rubens were addressing the Society on the fundamental investigations for which their names are best known. At the beginning of the War, the Society numbered more than seven hundred members, and the *Verhandlungen* were publishing papers of the first importance

After the War, the Society initiated fundamental changes, which increased its influence both inside and outside Germany Local branches were founded in all the chief centres of physical research throughout the country, and, in conjunction with the newly founded society for technical physics (*Deutsche Gesellschaft fur technische Physik*, in the foundation of which, if I may obtrude a personal note, my old friend Hausser, whose death in 1933 at the early age of forty-seven years was so widely lamented, played a prominent part), yearly meetings were arranged, somewhat similar to our British Association meetings, but for physics only The most recent of these meetings was held last September at Bad Pyrmont, and nearly five hundred physicists attended

Changes which were widely felt outside Germany were made in the publications of the Society There were in 1920 two extensive publications which gave abstracts of the world literature in physics, the *Fortschritte der Physik* and the *Beiblatter* of the *Annalen der Physik* In place of these a single publication was issued, the *Physikalische Berichte*, which has attained a high reputation, outside as well as within Germany The abstracts are, in general, exceedingly good, and appear promptly In the same year, 1920, the *Verhandlungen* were discontinued, and in their place appeared the *Zeitschrift fur Physik*, under the auspices of the Society This publication is so well known to physicists in Great Britain as not to need commendation

The Society is a powerful agent for the promotion of physical knowledge and for international accord and co-operation in the search for scientific truths It now numbers some fourteen hundred members, of whom almost a third live outside Germany Its work was never more important than now, and on its ninetieth birthday, which is being celebrated in Germany as a jubilee, it will receive the congratulations and good wishes of physicists of all nationalities

E N DA C ANDRADE.

Obituary

DR THEOBALD SMITH, FOR.MEM R S

WITH the death on December 11 of Dr. Theobald Smith, there has passed away a great figure in the science of animal pathology Much of his life was spent in research on veterinary science, and his work illustrates the natural intimate connexion between human and veterinary medicine, for his researches were of so accurate and fundamental a character that they made far-reaching additions to knowledge of disease both in man and the lower animals The breadth of his outlook was remarkable and many branches of pathology have been enriched by his keen insight.

Theobald Smith was born at Albany, N Y., in 1859, and after taking the degree of Ph D. at Cornell in 1881 and of M.D. at Albany in 1883, he was appointed director of the Pathology Laboratory of the Bureau of Animal Industry in the U.S. Department of Agriculture in 1884, and his earliest work was recorded in the annual reports of that department.

From 1896 until 1915 he was director of the Pathological Laboratory of the Massachusetts Board of Health and was professor of comparative pathology at Harvard University from 1896 until 1915, when he was appointed director of the Animal Diseases Branch at Princeton of the Rockefeller Institute, where he was emeritus professor at the time of his death

The quality of Theobald Smith's work was recognised throughout the world, and in 1932 he received the Copley Medal of the Royal Society He was a foreign member of the Royal Society, the Paris Academy of Sciences, the Danish Royal Society and honorary member of many other scientific societies He was awarded the Manson Medal of the Royal Society of Tropical Medicine of London, and received many other scientific honours.

The best known of Theobald Smith's discoveries was that of the relation of ticks to the disease known as Texas fever or red-water of cattle In 1889 Smith and Kilborne accurately described the causal protozoon, *Pirosoma bovis* (*Babesia bigemina*) and in 1893 they showed that the disease was transmitted from one animal to another by the tick *Boophilus* (*Margaropus*) *annulatus* This was the first instance in which a protozoal disease of a mammal had been proved to be transmitted by an arthropod The cycle of the protozoon was complicated by the fact that the tick, after sucking the blood of an infected animal, fell to the ground and laid its eggs on the grass, and not until the eggs had hatched, after weeks, or months, were fresh cattle infected by the bites of the larval ticks By this work many obscure features of this serious plague of cattle were explained and several entirely new factors in epidemic and epizootic disease were disclosed

The time when Theobald Smith began his work was one of rapid advance in bacteriology, especially in the direction of describing new bacteria associated with special diseases His observations were often of striking originality and related rather to the manner of action of bacteria, but they were often unheeded and forgotten, to be rediscovered later by others The discovery of new phenomena appears to have been his chief interest though the subjects at which he worked had eminently practical aims, and his career illustrates the fundamental value of informed and intensive observation by those engaged in work on practical issues It has come as a surprise to many to learn that with D E Salmon in 1886 he showed that a culture of bacteria killed by heat if inoculated into a warm-blooded animal—a bird—gave protection against a lethal dose of the same living micro-organism. This was the first recorded use of a dead vaccine, though the discovery is commonly attributed to Pfeiffer, who in 1896 began a long series of fundamental experiments on the same subject. Another early observation, reported in 1895–96, was the occurrence of a "peculiar disease" with deep and subcutaneous hæmorrhages causing the death of guinea pigs in four to eight weeks if they were fed only on oats and bran without any green food This appears to be the first description of scurvy in the guinea pig, which has been used as a valuable indicator of scorbutic diets in research on vitamins in recent years Smith, however, did not mention the similarity to human scurvy, but was concerned to show that this deficiency in the food led to the death of animals inoculated with a bacterium innocuous to guinea pigs fed on a normal diet.

In 1889 Smith began a series of investigations into the chemical products and growth requirements of bacteria, which were continued for many years and led to results of much practical and theoretical value in bacteriology The chief of those observations were on the differential fermentation of sugars, the reducing power of bacteria, and the oxygen and carbon dioxide needs of different species and races of these micro organisms Among the characters of bacteria which most interested him was their capacity for variation in virulence and in other ways In 1895–96 he published a paper on the existence of two kinds of tubercle bacilli exemplified by strains from a bear and a bull respectively, and in 1896 he correctly described the differences between human and bovine strains and the forms of disease which they produced, anticipating Koch's better-known statement on the same subject in 1901.

Another early but neglected observation, published by Smith with Reagh in 1903, concerned the non-motile varieties of certain motile bacteria, and the distinct agglutinins which were produced in animals for the flagella and bodies of the bacteria These important facts were rediscovered in 1917 by Weil and Felix Smith made a number of new observations on the culture of the diphtheria bacillus and on its toxin, and in 1910 he showed that balanced mixtures of toxin and antitoxin could be used to induce immunity to infection In this way he laid the foundation of the present methods of protecting man against diphtheria

Smith's zeal for the advancement of knowledge for its own sake is seen in the story of his discovery in 1904 of anaphylactic shock in the guinea pig resulting from a second injection of horse serum The symptoms had often been seen by others and wrongly interpreted This discovery he communicated to Ehrlich by letter, and the first publication on the subject was by Otto in 1906 in a paper on "Das Theobald-Smithsche Phänomen der Serum-überempfindlichkeit"

In 1922 appeared his work on the first milk or colostrum of cows which, if taken in the first two or three days of life, protected calves from otherwise dangerous infections From among his numerous other original investigations may be mentioned those on the form of streptococcal mastitis of cows which may convey serious infections to man through the milk, on the forms of contagious abortion in cattle due to ***Brucella abortus*** and to the ***Spirillum abortus*** which he discovered, and on sarcosporidia He continued at work in apparent health until last summer

In 1934 were published Smith's Vanuxem lectures on "Parasitism and Disease" in which he summed up the history and theories of parasitism and recorded his mature reflections on this fascinating theme, with little or no reference to the share which he himself had taken in its development.

Dr. J. Walter Leather

The death of Dr J. W. Leather on November 14 removes one of those who have been largely responsible, during the last forty years, for the development of scientific work in relation to Indian agriculture, and he cannot be allowed to pass away without some reference to his activities in this and other fields

Born in 1860, at Rainhill in Lancashire, he entered his father's chemical factory at St Helens after leaving school, and, when he had served an apprenticeship to chemical work there, he was sent, in 1883, to study chemistry under Kekulé at Bonn There he stayed three years and left in 1886 with the degree of Ph D On leaving the University, the appointment of senior assistant to Dr J A Voelcker, the consulting chemist to the Royal Agricultural Society of England, was offered to him, and he held this post for six years During this time he developed very high technical skill in chemical work in connexion with agricultural problems, a skill which he retained throughout his career He originated several new methods, and one of those—a process for the detection of castor seed in feeding-stuffs—is universally used at the present day. In 1891 he became professor of chemistry at the Harris Institute, Preston, but the call to his real life work in India came before he had really settled down there.

In 1892, as a result of the recommendations of Dr. Voelcker in his report on the improvement of Indian agriculture, the Secretary of State for India decided to appoint a chemist and an assistant chemist to the Revenue and Agricultural Department of the Government of India, and Leather was selected for the former appointment. It was in this appointment of agricultural chemist to the Government of India, and in that of Imperial agricultural chemist which followed it in 1906, that Leather did what may be considered his life work There he remained with few intervals until 1916, when he retired and settled down in Malvern

When Leather was appointed to India in 1892, the position he occupied led to his having to range the length and breadth of the country, studying and advising upon the various problems which were placed before him by the authorities of the various provinces. He was, in fact, the only chemist attached to all the agricultural departments in India His activity was tremendous, but it was an almost impossible position. His publications during this period (most of which appeared in the *Agricultural Ledger* then edited by Dr. Watt) were varied and numerous. They include the first general account of Indian soils, the first series of analyses of Indian manures, studies of alkali and salt lands, studies of sugar-cane and the composition of the Indian varieties, and a multitude of other questions. On the whole, the conditions under which Leather worked at this time did not permit him to push any of his many inquiries to a final issue in the improvement of methods or the better utilisation of Indian resources. A summary of his work during this first stage of his Indian career is contained in his final report on the first five years of the work of the Agricultural Chemist to the Government of India, issued in 1897

The more congenial part of Leather's Indian work came in 1904, when the Imperial Research Institute at Pusa was founded, and he settled down as the head of the chemical department at that Institute, as Imperial agricultural chemist As a result of his activities there, we have a series of publications, most of them published as memoirs of the Department of Agriculture in India These deal with such subjects as the water requirements of crops in India, the composition of Indian rain and dew, soil temperatures in India, the problems of drainage and the loss of water from the soil in the tropics, and the interaction of calcium carbonate and carbon dioxide in soil under tropical conditions It cannot be said that the work he did was of an epoch making character, but he gave us a very useful collection of data which did not exist before, and which nobody else has gathered together Within its limits, his results were always reliable, and for several generations many workers will bless the name of Leather for the careful observations which can form the basis for real agricultural advances to be initiated by others

So far as his work generally was concerned, Leather was essentially a laboratory worker Of his industry there was no doubt, while he had a great capacity for friendship, and there are many who look back to their association with him as a time when they were initiated into that close study of a limited objective which was the special characteristic of his work H H M

We regret to record the deaths on January 2, as the result of an accident in the Austrian Tyrol, of Mr Kenneth F Armstrong, aged twenty five years, and Mr John Howard, aged twenty-six years Mr. Armstrong was associated with his father, Dr E F Armstrong, in the preparation of monographs on the glycosides and the carbohydrates, and Mr Howard was a research worker at the Fuel Research Station, Greenwich

---

We regret to announce the following deaths.

Capt J E Bernier, known for his explorations of the Canadian Arctic, on December 27, aged eighty-two years

Sir Maurice Craig, consulting physician in psychological medicine to Guy's Hospital, on January 6, aged sixty-eight years

Prof. Roland B Dixon, professor of anthropology in Harvard University since 1916, an authority on the languages and culture of the Indians of the Pacific coast, on December 20, aged fifty-nine years

Sir Alfred Ewing, K C.B., F.R S, formerly professor of mechanism and applied mechanics in the University of Cambridge, lately principal and vice-chancellor of the University of Edinburgh, on January 7, aged seventy-nine years.

Mr J C. Lawson, University lecturer in classics in the University of Cambridge, an authority on Greek folk-lore, on January 5, aged sixty years.

News and Views

The Right Hon. Sir Herbert Maxwell, Bt, K T, F.R.S.

ALL who love Scotland, whatever may be the grounds of their affection, will join in the tribute of congratulation and wishes of good will to Sir Herbert Eustace Maxwell of Monreith on the celebration of his ninetieth birthday on January 8 He has shown himself a most loyal son of a race noted for pride in its motherland, and as much as any writer since the days of Sir Walter Scott, he has successfully interpreted to his fellow-countrymen, as well as to the southerner, the charm, never too obvious, of the Scottish countryside in all its variety, and the romance of the chequered and turbulent course of Scottish history Here he has ranged from the making of Scotland and the high adventure of the Bruce to the lowly annals of the hamlet, obscurely and imperfectly preserved in local tradition and place-names His numerous studies of national and local history, the latter especially in his own Galloway, deserve well of Scottish students, but archæologist and historian alike are no less indebted to him for his activities as president of the Society of Antiquaries of Scotland and as chairman of the Royal Commission on Scottish Historical Monuments in practical affairs relating to Scottish history and archæology Sir Herbert's literary achievement has covered a wide field—from romance and fiction, history and biography, including a life of the Right Hon W H Smith and a survey of the first sixty years of Queen Victoria's rule, to "British Freshwater Fishes", but he is most at home when he seeks to convey the interest and charm of the birds and beasts of his own countryside, the trees of the woodlands and the flowers of a Scottish garden Here, indeed, *nihil tetigit quod non ornavit*

Prof. D'Arcy W. Thompson, C.B., F.R.S.

ON December 23, Prof D'Arcy Wentworth Thompson completed the fiftieth year of his tenure of a professorial chair, for he was appointed professor of biology in the newly founded University College of Dundee in 1884. Fresh from the biological renascence in Cambridge under Michael Foster and Frank Balfour, the young professor found in Dundee every possible kind of discouragement, scanty endowment, mean and unsuitable buildings—and the depressing atmosphere of an industrial city The title of his chair was soon changed to that of zoology, and in the closing years of the century the incorporation of the College in the University of St. Andrews, and the establishment of a medical school, brought a small increase in the number of his students. In 1917, on the retirement of his senior colleague, Prof W. C M'Intosh, D'Arcy Thompson was transferred to the chair of natural history, which he still occupies, in the United College at St Andrews. Fortunately, the time has not yet come to sum up or to pass judgment upon D'Arcy Thompson's achievements. His innumerable friends, however, and his pupils—none too numerous, alas !—will join with us in congratulating him on the jubilee of his professorship Few men of our time have been so much at home in both the fields of the old and the newer learning He is, we believe, the only holder of a chair of science who has been president of the Classical Association, and there must be many among those that have passed through his class-room, who found in an elementary course of lectures on zoology at least the beginnings of a liberal education

A National Institute of Science for India

THE Calcutta correspondent of *The Times* reports on January 7 that —"The Governor of Bengal has inaugurated a National Institute of the Sciences of India, of which the object is to promote scientific knowledge in India The institute will act through national committees, and will serve as a national research council for the undertaking of work of national and international importance required by the public and the Government Dr L. L Fermor, Director of the Geological Survey of India, is the first president " From this report it would seem that the new body is to combine the characteristics of a National Academy of Sciences and a National Research Council, but it is difficult without further details to know how it is related to existing organisations in India

IT may be remembered that in 1930 an Academy of Sciences was formed in the United Provinces, with its seat at Allahabad Later, there was a movement for the establishment of an Indian Academy of Sciences through the development or affiliation of the U P Academy or by the formation of a new body It was suggested that the ancient Asiatic Society of Bengal might appropriately become such an All India institution, and with the view of considering the whole matter a committee was appointed by the Indian Science Congress to prepare a report Without awaiting the recommendations of this Committee, Sir C V Raman, now director of the Indian Institute of Science, Bangalore, himself registered the title of "The Indian Academy of Sciences", and the *Proceedings* of this Academy, similar in format to those of the Royal Society of London, began publication in July last There are thus now two academies of sciences in India—one in Allahabad and the other in Bangalore, that is, in north and south India respectively There is plenty of room in the country for these two academies, but objections can be raised to either of them assuming the sole right to use the prefix "Indian", and it is not surprising, therefore, that Sir C. V Raman's action has caused a storm of protest No doubt the claims of different societies and places in India to recognition as centres of publication for the whole country have been considered by the committee of the Indian Science Congress. We await with interest the recommendations of the committee and trust that they will assist in removing the confusion which at present exists and will promote unity of purpose among scientific workers in all parts of the country.

British Art in Industry

ON Friday, January 4, the Prince of Wales opened an Exhibition of British Art in Industry at the Royal Academy, Burlington House It is to remain open until March 9, and has been organised jointly by the Royal Academy and the Royal Society of Arts The chief aim of this large-scale experiment is to show the public that British manufacturers of textiles, glassware, furniture, etc, are alive to the importance of consulting artists, when designing their products The part played by science in rendering it possible to realise this ambition is not referred to nor perhaps could it be within the limited space available at Burlington House But the scope of the exhibition is wide, and especially striking is the increasing use made of synthetic resins such as bakelite in the manufacture of a great variety of household things Imperial Chemical Industries, Ltd, show a new form of this colourless plastic material (called Resin M) which it is claimed actually exhibits the sheen found in certain transparent natural crystals, and which can be carved and shaped into many beautiful objects The glass exhibit, too, is particularly important and interesting Then there are sets of furnished rooms of modern design, together with a vast display of fabrics, as well as some beautiful jewellery and metal work

THE alliance of activities referred to above is assisted by the publication of an abridged account of the aims and work of the Royal Society of Arts, issued by and under the ægis of the Council of the Society, entitled "The Story of the Royal Society of Arts" (London John Murray, 1935 *3s 6d*) We read that in 1753, one William Shipley, residing at Northampton, published certain proposals for raising by subscription a fund for distribution through premiums, for the promotion of improvements in the liberal arts and sciences, manufactures, and so on Whereupon, in 1754, a Society came into being for the "Encouragement of Arts, Manufactures and Commerce in Great Britain" The organisation had no exact prototype at the time, and was under the obligation (like the later movement elsewhere by Count Rumford), of going forward, or going under It succeeded in the former process, and has thus achieved a hundred and eighty years of existence, which, however, have included interludes of vicissitudes Here we must leave reminiscent records to speak for themselves But it remains to recall that the Prince Consort became president of the Society of Arts in 1843, and was in office at the time of his death in 1861 Prince Albert's foresight and initiative were of signal value, since his death the interest of our Royal Family has been steadily maintained, strengthened and broadened in recognition of the Society, its aims of the present, and its outlook upon the future

Eumorfopoulos Collection

THE announcement by Sir George Hill and Sir Eric Maclagan that the British and Victoria and Albert Museums, assisted by the National Art-Collections Fund and other donors, have secured the Eumorfopoulos collection for the nation is a source of intense gratification to a wide circle Not only is the collection of Far Eastern art made by Mr. George Eumorfopoulos the finest in existence, but also the combination of informed taste, opportunity and the necessary financial resources which has made its assembly possible is not likely to recur. The aesthetic, historical and scientific significance of these examples of the artistic activities in every form and material of the peoples of the Far East, and more especially of the Chinese, from the first millennium B C onward, has been made widely known by the generosity of its owner, as well as in monographs devoted to the study of specific examples or of classes of objects In future, a collection of the highest educational value will be available for the instruction of a wider public, more especially if as a whole or in part it should be incorporated in the much desired central Museum of Asiatic Art, which this acquisition may have brought a stage nearer Nearly one half the purchase money is available to be handed over forthwith to secure the immediate possession of a proportionate part of the collection An early and ready response to the appeal of Sir George Hill and Sir Eric Maclagan for contributions towards the balance of the cost will be a graceful recognition of the public spirit of the owner in accepting a relatively low figure for what is, in effect, a priceless collection

Professional Men and Research

AN address entitled "A Talk about Research" was delivered by Mr W P Elderton to the Institute of Actuaries Students' Society on November 19 and has now been published The details of the address were highly technical, but the general principles laid down seem to be applicable to any profession, though they are on rather different lines from those suitable for workers in pure science at universities or research institutes Many young men would like to undertake some kind of research work, but they find it difficult to think of suitable subjects Of course, a genius would find his own problems and solve them Leaving aside such, as needing no guidance, some general advice can be given to those less original One way of starting consists of a study of the history of ideas on a certain subject, taking care to examine French and German sources as well as English This study will often reveal the inadequate foundation of current theories, and it will then naturally lead on to the attempt to replace the weak portions by something sounder. Another profitable and indeed indispensable task is the reconsideration of the professional practices that were established as the best in the past, in view of the change in contemporary conditions. Mr. Elderton warned his hearers against a hurry to rush into print. They should endeavour to take all possible precautions against error before publication, and to write in good English, so as to be intelligible to any diligent, well-informed reader. Controversy should be avoided, and when they think another writer has made a mistake, they should try to follow his line of thought and consider carefully whether the

mistake is not their own. The advice of Francis Galton, "Never resent criticism and never reply to it", is good, though hard to follow by those not possessing Galton's saintly disposition and philosophical calm

Statistics and Inductive Inference

IN a paper read before the Royal Statistical Society on December 18, Prof. R A Fisher surveyed the recent change in the outlook of mathematical statisticians The most profound modification seems to have taken place rather in the logical than in the mathematical aspect, though it has been brought about by the resolution of mathematical difficulties Statisticians are now dealing with types of uncertain inference wider than those of the theory of probability Prof. Fisher expressed the view that the current teaching of pure mathematics is not an altogether adequate preparation for fruitful work in this field, for this teaching is purely deductive, omitting the essential concepts of inductive logic, and insists on 'rigour' in a limited sense which he considers very inadequate to the requirements of an inductive problem The questions raised by Prof Fisher are of great interest and importance, but it should not be overlooked that there is still some difference of opinion concerning them, as will be seen by a perusal of the series of papers in the *Proceedings of the Royal Society* (1932–4) by Dr H Jeffreys

Early Man in North America

DR FRANK H H ROBERTS, JR, according to a communication issued by the Smithsonian Institution, Washington, D C., has discovered in the foothills of the Rocky Mountains, in northern Colorado, a habitation site and factory of 'Folsom' man This discovery is of the greatest importance for American archæology, as not only is it the oldest known habitation site in America, but it is also the first occasion upon which there has been any indication of the mode of life of the peoples by whom the 'Folsom' points were made, beyond the bare fact that they were hunting tribes of a high antiquity —a deduction from the association of these points with the bones of extinct bison, musk ox and mammoth, known to have pastured at the edge of the ice-sheet The 'Folsom' points, it will be remembered, were first discovered five years ago at Folsom in New Mexico, and since then these finely-chipped flint implements have been found, frequently in association with extinct mammals, all over the United States from New Mexico to Virginia and Pennsylvania. It is thought by some authorities that they point to the existence of man in America several thousand years earlier than had previously been supposed Dr Roberts's discovery provides something of a cultural background for these scattered finds. The site he has now discovered rests upon a hard, chalk-like formation with about fifty feet of alluvial deposits above it. These must have been laid down very slowly. It is about a quarter of a mile in extent, but as yet only a small part has been excavated. The relics represent several camp sites occupied over a period of years. Flint nodules from which the implements were manufactured are plentiful Thirty characteristic points and a great variety of scrapers, rough stone blades, drills, engraving tools and hammerstones, with a large number of broken animal bones, have been collected

Antiquity

WITH its December issue, *Antiquity* completes its eighth year. The editor of the only free-lance journal entirely devoted to archæological matters is to be congratulated on his success in having carried through this enterprise successfully and without the assistance of any official organisation, in a period of exceptional difficulty. While there is undoubtedly a considerable public which is interested in archæological discovery up to a point, to hold that interest requires both tact and judgment The editor, whose aim is to present to his readers scientifically sound and accurate information of the latest movements in archæological discovery in a popular form, has a difficult course to steer, if he is to avoid the appeal to the sensationalism which flavours the news of 'finds' as it appears in most of the daily Press. On the other hand, the editor of *Antiquity*, both by his own 'tilting' in his unconventional notes and otherwise, encourages his contributors to an engaging freedom of treatment which in itself adds no little attraction to the pages of his periodical The contents of *Antiquity* of December illustrate these qualities admirably. If, for example, Mr Noel Myres' criticism of Dr Mortimer Wheeler's article in a previous issue on the topography of Saxon London ventilates further a subject which is of perennial interest to a wide circle, Dr. Wheeler's reply will appeal equally to those who appreciate learning worn lightly. Among the remaining contents of this issue, which are as a whole no less attractive, it is, perhaps, permissible to refer to the contribution by Sir George Macdonald on the Romans in the Middle East, which is an illuminating commentary on M A Poidebard's recently published air survey of the Roman frontier in Syria Like its predecessors, this issue fully supports the editor's appeal for an extended circulation to ensure the continued existence of a publication which is doing excellent work for archæological science by keeping its achievement before a wider public than is reached through channels of a more formal nature.

Thermo-remanence of Bricks

A LETTER has been received from Mr T. G. Bocking, Princes Chambers, 6 Corporation Street, Birmingham, 2, giving an account of some observations on the magnetic properties of bricks. Bricks were selected from a number of South Staffordshire kilns, the direction in which the bricks were lying when baked being noted. The polarity was most clearly marked when the bricks had been lying in a north-south direction, and it was found that the bricks were magnetised approximately along the line of magnetic dip. Among the bricks examined were

some made from Etruria marl, containing about 11 per cent iron oxide. The kiln temperature was 1150° C. The content of iron oxide (mainly Fe_2O_3), to which such ferromagnetic properties may be attributed, varies considerably in the materials from which bricks are made. It is usually well below 2 per cent in the fire clays giving white and cream bricks, about 7 per cent in the clays giving red bricks, and 10 per cent or more in those giving blue and black bricks Among recent relevant investigations are those of Koenigsberger (*Phys Z*, 33, 468, 1932) on hæmatite (Fe_2O_3), magnetite (Fe_3O_4) and other ferromagnetic compounds He finds that hæmatite, when cooled down in the earth's vertical field (0 4 gauss) from above the Curie point (about 670° C), shows a residual magnetisation which approaches the saturation remanence, and may be a considerable fraction of the saturation magnetisation It is, of course, not possible to generalise about bricks Each set of bricks presents a special problem, and precise discussion of the magnetic properties would require a detailed knowledge of the chemical composition of the clays, and of the conditions of baking and cooling It is, however, probably not widely realised that most bricks are magnets—though feeble ones, and Mr. Bocking's observations are of interest in indicating that the phenomenon of thermo remanence may be demonstrated with such a common object as an ordinary brick

A Remarkable Cloud Form

A PHOTOGRAPH of a remarkable cloud, of which a reproduction is shown in Fig 1, has been received from Prof. I. S. Astapowitsch, of the Astronomical Institute, Fontanka 34, Leningrad It was observed some time in 1932 at Stalinabad (lat 38° 34′ N., long. 68° 47′ E) above the Hissar Valley, and is described as having a rotational movement. Rotation round a vertical axis is strongly suggested by the appearance in the photograph of the middle and upper parts of the cloud. Students of cloud

FIG. 1

forms will recognise at once the very unusual character of this cloud, which has some structural resemblance both to the cumulo-nimbus cloud associated with a thunderstorm and to the funnel cloud of the tornado. By a curious coincidence, in a recent number of the *Meteorological Magazine* (Nov. 1934, vol. 69, No. 826) a sketch is shown of a cloud observed on October 4, 1934, near Waltham Cross, Hertfordshire, by Mr. Donald L. Champion, which has strong points of resemblance to the cloud just described. In each case a strong upward growth appears to have taken place over one part of a rather flattened cumulus cloud, the base of which was inclined to be convex, the central parts appearing to be lower than those farther from the centre. In the cloud near Waltham Cross the rapid vertical extension was formed in a few seconds, and after about five minutes the mushroom-shaped top spread out horizontally to form an 'anvil' cloud like those so often seen over thunder clouds In both cases it is likely that opposed wind currents and convexion, perhaps associated with local heating, may have combined to produce rapid ascent of air with otation.

Distribution of Birds at Sea

MOST ocean travellers must have noticed the very irregular distribution of birds on the open sea on different days, notwithstanding the apparently similar conditions of air and ocean Censuses made during the crossing of the Atlantic record statistically these differences, but little attempt has been made to suggest a satisfactory reason for them It seems very likely, however, that the presence or absence of pelagic birds is regulated by the oceanic currents, as S C Brooks suggests in the *Condor* (September 1934, p 185) Oceanographers have shown that where the Arctic Current meets the North Atlantic Drift, there arise complexes of eddies and upwelling of the under waters, and that at the margin of contact there is a surface display of abundant organisms which attract fishes and other predators This congregation of plenteous foodstuffs in limited areas may well attract pelagic birds, and Jesperson has already shown that there is a general connexion between the numbers of birds seen in a particular area at sea, and the quantity of macro-plankton in the surface waters Pushing the probabilities further, it is likely that the migrations of oceanic birds may be related to the movements of plankton, by whatever determined, and tentatively Brooks makes the very interesting (but quite untested) suggestion that one of the factors which guided the homing terns of Bird Key from Cape Hatteras, to which they had been conveyed, back to the Tortugas, may have been the rich feeding grounds along the margin of the Gulf Stream ' He adds that perhaps other factors too must be considered, such as the density of the air, which has been regarded as determining the northern limit of the distribution of the southern Atlantic wandering albatross.

Flora of West Lancashire Dunes

FOR some time, increasing concern has been felt amongst the botanists and Nature-lovers of this area for the dangerous position of the unique flora of the dunes of west Lancashire, particularly around Ainsdale. Recently two representatives of the Flora's League—a society for the preservation of wild flowers—

Dr. C. T. Green, president of the Liverpool Botanical Society and author of "The Flora of Liverpool", and Mr. Eric Hardy, librarian of the Liverpool Naturalists' Field Club, made a special survey of the present status of the flora, with the consent of the Royal Society for the Protection of Birds, to find whether the latter's sea-bird sanctuary on the dunes is also serving as a wild flower sanctuary. The dunes are unique for their profusion of *Pyrola rotundifolia* (round-leaved wintergreen) and *Parnassia palustris* (grass of Parnassus), probably more numerous there than anywhere else in England, and these flowers have been banned from the wild flower collecting sections of the Southport flower show in order to protect the dunes. The duneland orchid (*Epipactis dunensis*), which so far has not been recorded from any other part of the country, was found growing abundantly on the dry dunes, beside the pinewoods, and in the thinner pinewoods, its only enemy being the rabbits. The area is rich in Orchidaceæ. According to the records of the Liverpool Flora Committee, *Erythræa latifolia*, the broad leaved centaury, which was first described from those sandhills by Shepherd and Bostock a century ago and has not been recorded from any other part of the country, is extinct, though profuse enough at the time of its discovery. The last specimen gathered from the sandhills at Formby is now in the collection at the British Museum (Natural History).

Electrical Calculating Machine for Simultaneous Equations

A MECHANICAL calculating machine for solving simultaneous linear equations up to ten in number under construction at the Massachusetts Institute of Technology by Drs. V. Bush and J. B. Wilbur was referred to in NATURE of December 8 (p. 877). An electrical machine designed for the same purpose, also working up to ten equations, has already been designed by R. R. M. Mallock and constructed by the Cambridge Instrument Co., Ltd. A full account of this machine has been published (*Proc. Roy. Soc.*, A, **140**, 457, 1933) and a note on it appeared in NATURE of June 17, 1933 (p. 880). The machine itself is set up and at work in the Engineering Laboratory, Cambridge. It is stated that this machine can determine rapidly a set of roots to an accuracy represented by about 0·1 per cent of the largest root in favourable cases when the equations are well conditioned. The fundamental principle of the machine is to use a number of alternating current transformers, the coils of which are coupled up to such numbers of turns as to represent a set of equations of condition for the fluxes through the transformers which are the linear simultaneous equations to be solved. Such machines promise to be of great value in the very large number of problems which can be reduced to the solution of such sets of equations.

Physiographic Map of Japan

AN instructive physiographic map or diagram of Japan on a scale of about 80 miles to an inch is published by Dr. G. T. Trewartha in the *Geographical Review* of July. Japan lends itself to this treatment since about seventy-five per cent of the land is mountainous and the lowlands are mainly peripheral. The diagram brings out in a striking way the contrasts between the main structural regions of Japan, that is to say, the inner and outer zones running the length of the islands and meeting in fault scarps and tectonic depressions, except in central Honshu where the great zone of depression cuts across the country and the rift is partly filled by later accumulations. The outer zone of Pacific fold mountains appears as a series of well-developed longitudinal ridges and valleys with few noteworthy plains, but separated in the south by subsidence into isolated mountain masses. By contrast the inner zone appears as a rugged hill country of dissected block plateaux, some upheaved and others depressed with much volcanic activity. The Inland Sea forms a notable area of depression in this zone.

Tibet Earthquake of January 3

AN earthquake of moderate intensity occurred in southern Tibet early on January 3. According to the report issued from Kew Observatory, the first movements were recorded there at 2h. 0m. 58s., G.M.T., and at Bombay at 1h. 54m. 23s. The epicentre was estimated to be 4,600 miles from Kew and 1,150 miles from Bombay, or in about lat. 30° N., long. 88° E., the time at the origin being 1h. 50m., G.M.T. The earthquake, though not of unusual intensity, is interesting as its epicentre lay about 120 miles to the south of that of the great earthquake of last December 15 (NATURE, **134**, 963, Dec. 22, 1934).

Third International Congress of Soil Science

THE Third International Congress of Soil Science will be held in Oxford, on July 30–August 7 this year, under the presidency of Sir John Russell. The two previous congresses of the series were held in Washington in 1927 and in Leningrad and Moscow in 1930, and were notable for the exceptionally international character of the personnel and the discussions. The Congress will meet as a whole in six plenary sessions, at which a general survey of recent advances in every branch of soil science will be made, and it will also work in sections or 'commissions' dealing specifically with (1) soil physics, (2) chemistry, (3) biology, (4) fertility, (5) classification, and (6) technology. Three sub-commissions will discuss problems relating to alkali, forest and peat soils respectively. A 16-day excursion round Great Britain leaving Oxford immediately after the Congress, and terminating in Cambridge on August 23, is being arranged for the benefit of members wishing to obtain first-hand knowledge of British agriculture and soils. Every member of the Congress will receive a copy of the official transactions, including the full text of papers read at the plenary sessions, and detailed reports of the discussions at the Commission sessions. The cost of the transactions will be included in the Congress fee (£2), payment of which will also entitle members to attend all meetings, receptions, etc., held in connexion with the Congress. College accommodation during the Congress can be

reserved through the Organising Committee Intimation of attendance at the Congress should be sent as soon as possible to the Secretary of the Organising Committee, Mr G V Jacks, Imperial Bureau of Soil Science, Harpenden, England, from whom all further information may be obtained

International Botanical Congress

A PRELIMINARY programme has been circulated of the Sixth International Botanical Congress, to be held in Amsterdam on September 2–7 of this year, under the presidency of Prof. F A. F C Went. An executive committee of Dutch botanists, with Dr M J Sirks of Wageningen as secretary, has divided the Congress into ten sections agronomy, cytology, genetics, geobotany, morphology and anatomy, mycology and bacteriology, phytopathology, palæobotany, plant physiology, taxonomy and nomenclature The presidents and vice-presidents of sections are already announced, as well as the topics chosen for discussion in each section, and some of the principal speakers The subjects for discussion include many of the current problems in all phases of botany, and some will be considered jointly by two or more sections A number of excursions to various parts of Holland are being arranged to follow the Congress

Announcements

THE second award, by the Wilhelm Roux Stiftung fur Entwicklungsmechanik, of the medal founded in commemoration of Wilhelm Roux, who died on September 15, 1924, has recently been made to Dr Jan Boeke, professor of histology in the University of Utrecht, for his researches on the development of the nervous system

SIR LEONARD HILL writes "In my letter on 'The 1933 Everest Climbing Expedition and Oxygen' [NATURE, Dec 22, p 969], I say 'animals cannot live for more than six weeks' in oxygen equal to 10 per cent of one atmosphere. The words 'without serious deterioration' should have been added"

THE Royal Photographic Society, 35 Russell Square, W.C.1, is now holding its sixth exhibition in the series, "Photography in the Service of Mankind" The present exhibition is devoted to exploration and travel, and includes records from most of the great expeditions which have taken place during the last fifteen years The Exhibition will remain open to the public on week-days from 10 a m. to 6 p m until January 31

THE Iron and Steel Institute, in co-operation with other societies and technical institutions, will hold a symposium on the 'Welding of Iron and Steel" on May 2–3 The symposium, which will be held in connexion with the annual meeting of the Institute, will take place in the lecture theatre of the Institution of Civil Engineers, Great George Street, Westminster, London, S W.1 Further information can be obtained from the Secretary, Iron and Steel Institute, 28 Victoria Street, London, S.W.1

THE annual general meeting of the Institute of Metals will be held in London on March 6–7. On March 5, there will be an additional session with other technical institutions when a discussion will take place on "Problems of Cold Presswork", to be opened by Dr H J Gough. The discussion will be held at the house of the Royal Geographical Society. The annual May Lecture of the Institute will be delivered by Prof W L Bragg, whose subject will be "The Atomic Arrangement of Metals and Alloys". The annual autumn meeting of the Institute will be held in Newcastle-on-Tyne Further information can be obtained from the Secretary, 36 Victoria Street, London, S W.1

THE French Society for the Propagation of Cremation, founded in 1880, has nominated as its president Prof G Barrier, formerly president of the Academy of Medicine, in succession to the late Prof Léon Bernard, and Dr. G Ichok as general secretary. The offices of the Society have been transferred to 10 rue Fanny, Clichy, Seine

A COURSE of six public lectures on different aspects of "Time" will be given at Bedford College, commencing on January 17 The lecturers will be Prof F. C Bartlett (January 17), Dr. J K Fotheringham (January 31), Lieut-Comm R T. Gould (February 14), Dr R. A. Sampson (February 28), Sir Arthur Eddington (March 7), and Prof C D Broad (March 14) Cards of admission can be obtained from the Secretary, Bedford College, Regent's Park, N W.1

PROF F E FRITSCH, of Queen Mary College, London, has completed the first volume of the first comprehensive account in the English language of the morphology of the Algæ It is entitled "The Structure and Reproduction of the Algæ", and is designed for use by university students as well as by research workers The book will be published this month by the Cambridge University Press

A COMPREHENSIVE catalogue of zoological material for use in schools and colleges has been issued by Messrs E Gerrard and Sons, 61 College Place, London, N W 1 The 64 pages contain very complete lists of stock species, from Protozoa to mammals, for examination or dissection, of mounted specimens, injected and dissected, cartilaginous skeletons, and life-histories Prices are moderate, and our experience of the preparations, all of which are made by Messrs. Gerrard, is that they are of reliable quality

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—A lecturer in agriculture and warden at the Kent Farm Institute —The Principal, Kent Farm Institute, Borden, Sittingbourne (Jan. 21) A full-time physicist in the London County Council's Hospital Service—The Clerk of the Council, County Hall, Westminster Bridge, S.E 1 (Jan 25). A keeper of the Department of Geology in the public museums of Liverpool—The Town Clerk, Municipal Buildings, Dale Street, Liverpool, 2 (Feb. 5) A University professor of physiology at St. Mary's Hospital Medical School—The Academic Registrar, University of London, S.W 7 (Feb. 15).

Letters to the Editor

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 72

Disintegration by Slow Neutrons

FERMI and his collaborators[1] have reported that neutrons slowed down by collisions in substances containing hydrogen are captured by many nuclei very much more frequently than are fast neutrons. In the cases reported, the process is one of pure capture, resulting in the formation of a higher isotope It is to be expected that slow neutrons may cause a nuclear transformation with the emission of heavy particles if energy can be released in the process The probability of such a reaction will depend on the mutual kinetic energy and potential barrier of the resulting particles, and may be large when these quantities are of the same order of magnitude, this can in general only be expected for elements of low atomic number

We have examined some of the lighter elements for such transformations. The general procedure was as follows The element under examination was enclosed, as target or as gas, in an ionisation chamber connected to an amplifier and oscillograph and exposed to the bombardment of neutrons from a radon-beryllium source A small number of ionisation 'kicks' was always observed, due mainly to recoil particles The source and chamber were then surrounded by paraffin wax, thus exposing the target or gas to the bombardment of slow neutrons In some cases, notably those of lithium and boron, a very large increase in the number of 'kicks' was observed, indicating that a nuclear transformation was taking place

With lithium, the kicks observed were of two kinds, one due to doubly charged particles and one to singly charged particles. By covering the lithium target with aluminium foils we found that the singly charged particles had a maximum range of about 5·5 cm in air, and that the range of the doubly charged particles was less than 1·5 cm. This suggests that the particles arise from the reaction

$${}_3\mathrm{Li}^6 + {}_0n^1 \longrightarrow {}_2\mathrm{He}^4 + {}_1\mathrm{H}^3.$$

From the masses of the nuclei concerned, an energy release of about 5 million electron volts is expected, and a range of the H^3 particle which agrees well with that observed.

In the case of boron, the majority of the particles appear to be doubly charged and to have ranges less than 5 mm. in air. The only reaction which appears to fit the facts is

$${}_5\mathrm{B}^{10} + {}_0n^1 \longrightarrow {}_2\mathrm{He}^4 + {}_2\mathrm{He}^4 + {}_1\mathrm{H}^3.$$

A small but definite effect has been observed with nitrogen, and a rather doubtful effect with beryllium.

The most interesting feature of these reactions is their very high probability. The cross-section[2] for capture of a slow neutron by Li^6 or B^{10} appears to be of the order of 10^{-21} sq. cm., a magnitude which suggests that there is an attractive force between a nucleus and a neutron at relatively large distances The above reactions afford a convenient and sensitive means for detecting the presence of slow neutrons

Metaplasia of Uterine Epithelium Produced by Chronic Œstrin Administration

THE synthesis of polycyclic compounds possessing both œstrogenic and carcinogenic properties[1], the finding of considerable amounts of œstrin in cancerous tissue[2] and in the blood of tumour-bearing male mice[3], and the demonstration in various ways of a correlation between the amount of œstrin present in the body and the incidence of spontaneous mammary carcinoma (in susceptible strains of mice)[4] have led many students to suspect an interrelationship between epithelial growths and the female sex hormone. Metaplasia from columnar to stratified epithelium in the seminal vesicles and coagulating glands of male mice and rats treated with œstrin has been noted[5,6,7], but analogous effects in female animals have not been reported Overholser and Allen[8] have found that treatment with œstrin and corpus luteum hormone enhances the atypical epithelium proliferation produced by traumatisation of the cervix uteri in monkeys; but since this proliferation occurred in a region in which squamous epithelium is normally present, it cannot be said whether metaplasia occurred or not.

Recently, a series of experiments were planned with the view of determining to what extent the 'anti-hormone' theory[9] might be found applicable. In one of these a group of eight female castrates were injected daily intraperitoneally with 30–60 γ of œstrone in oil (crystalline folliculin, kindly supplied by Dr. Girard) over a period of ten weeks. The mammary glands showed marked duct proliferation with some formation of alveoli, the degree of development was the same in biopsy specimens removed two weeks after the beginning of treatment as at the end of the experiment. Biopsy specimens also showed that the uterus and vagina preserved their œstrous development throughout the whole period. The experiment therefore confirmed the statement of D'Amour[10], that loss of sensitivity to œstrin does not occur. But when the animals were killed after ten weeks treatment, histological examination of their uteri showed in four cases a more or less complete metaplasia of the cylindrical secretory epithelium into a stratified squamous epithelium with cornification, from which irregular buds penetrated deep into the stroma.

In another experiment, 0·1–0·3 c.c. of 0·1 per cent œstrone in corn oil was placed in one horn of the uterus of each of six adult castrate female rats, escape of the oil being prevented by ligation of the uterus; the animals had previously been treated with moderate doses of œstrone intraperitoneally in order to distend the uteri. The animals were killed on the fourth day after filling the uterus; the œstrin-treated horn showed signs of commencing metaplasia in three cases and complete metaplasia to stratified squamous epithelium in one case.

Production of Electron-Positron Pairs

THE production of a pair of positive and negative electrons by two photons was one of the consequences of his theory of the electron first considered by Dirac. This effect is essentially at the basis of all pair production phenomena, and it may be of interest to point out that from the formula for it, recently given by Breit and Wheeler[1], we may readily deduce, to a certain approximation, the probabilities for the production of pairs by high-energy photons and electrons in the field of an atomic nucleus. The correlation of these effects depends on the fact that for an observer moving relative to a nucleus with a velocity approaching that of light, the field of the nucleus is approximately equivalent to a radiation field. In the region effective for producing pairs—at distances from the nucleus of the order of and greater than $\hbar/mc$—the nuclear field corresponds, for an observer travelling with velocity v, to a distribution of photons the number of which in the frequency interval $d\nu$ is given by

$$N(\nu)d\nu = (2/\pi)\alpha Z^2 \log(g\gamma mc^2/h\nu)\, d\nu/\nu \qquad (1)$$
$$\alpha = e^2/\hbar c, \quad \gamma = (1 - v^2/c^2)^{-1/2}, \quad g \sim 1$$

The cross-section, σ, for pair-production by a photon, $h\nu$, of energy ξmc^2, $\xi \gg 1$, is now obtained by considering its interaction with the photons, which, according to (1), represent the nuclear field. For a system S', moving with the incident photon with a velocity such that the energy of the photon is reduced from ξmc^2 to mc^2, the expression for σ thus obtained is

$$\sigma = \int_{h\nu = mc^2}^{h\nu \sim \xi mc^2} \sigma(\nu) \times (2/\pi)\, \alpha Z^2 \log(g\xi\, mc^2/h\nu)\, d\nu/\nu. \qquad (2)$$

$\sigma(\nu)$ is the cross-section for pair-production by a photon of energy $h\nu$ and a photon of energy mc^2, travelling in opposite directions. The second factor is the number of virtual photons in the nuclear field with frequency in the range $d\nu$. On substituting for $\sigma(\nu)$ the expression given by Breit and Wheeler and integrating, this gives

$$\sigma = (28/9)\, \alpha Z^2 (e^2/mc^2)^2 \log g\xi, \qquad (3)$$

which agrees with the result obtained by Heitler and Sauter by direct application of Dirac's theory. In this formula, and also the other formulæ given in this note, g is used to denote a numerical factor of the order of unity. Its exact value in the different cases cannot be derived by the present method and this represents the degree of approximation involved.

The production of pairs in collisions between two electric particles may be deduced in a similar way, either by replacing the field of both particles by radiation and using the Breit-Wheeler formula, or only the field of one and using the Heitler-Sauter-Bethe[2] formula. Adopting the second procedure we obtain, as the cross section for the production of a pair, of energy between εmc^2 and $(\varepsilon + d\varepsilon)mc^2$ (including energy of mass), by an electron of energy ξmc^2, in the field of a nucleus, Ze,

$$\sigma(\varepsilon)d\varepsilon = (28/9)\, \alpha Z^2 (e^2/mc^2)^2 \log(0{\cdot}15\varepsilon) \times (2/\pi)\, \alpha \log(g\xi/\varepsilon)\, d\varepsilon/\varepsilon, \qquad (4)$$

being simply the product of the Heitler-Sauter-Bethe formula and (1) (remembering that for an electron $Z = 1$). If $\varepsilon \gg 137Z^{-1/3}$, then in the first logarithmic term in (4) we must replace $0{\cdot}15\varepsilon$ by $179Z^{-1/3}$, on account of the effect of shielding.

The cross-section for the production of a pair of any energy, according to (4), is

$$\sigma = \int_2^{\sim\xi} \sigma(\varepsilon)d\varepsilon = (28/27\pi)\, \alpha^2 Z^2 (e^2/mc^2)^2 (\log g\xi)^3. \qquad (5)^*$$

Regarding the pair-production by a high energy photon, it is of interest that, in the system S', to which (2) explicitly refers, the pair-production is practically all due to the interaction of photons of energy of the order of mc^2. This results from the fairly rapid convergence of the integral in (2), the integrand being asymptotically proportional to ν^{-2}. This is quite analogous to the state of affairs in the problem of radiative collisions, where the use of the Klein-Nishina scattering formula on the same lines as the present use of the Breit-Wheeler formula, shows that the emission of radiation by a high energy electron in a nuclear field may be reduced to the scattering of radiation of quantum energy[3] $\sim mc^2$. Both the pair-production formula and the radiative formula have thus a very simple theoretical basis.

A fuller discussion of the contents of this note and of other effects of charged particles which may be correlated with radiation effects will shortly be published in the *Proceedings* of the Danish Academy.

Copenhagen.
Nov. 13.

* (4) gives only the order of magnitude of $\sigma(\varepsilon)$ if $\varepsilon \sim 1$ or $\varepsilon \sim \xi$. These regions of ε are, however, not important to the integrated cross-section. It might be remarked that (5) is in harmony with the results for pair-production by 2 particles obtained by Landau and Lifschitz by direct application of Dirac's theory, in so far as their calculations are published (NATURE, **134**, 109, July 21, 1934).

Absolute Value of the X-Unit

IN order to determine the ratio between the X-unit and the absolute unit of length, I have registered certain X-ray lines in high orders with a concave glass grating ($R = 5$ m.) and determined their wavelengths by comparing them with known spark lines in the first order, registered on the same plate[1]. The X-ray line which turned out to be most suitable for such relative measurements was the aluminium $K\alpha_1\alpha_2$ line, which has been determined very accurately by Larsson[2] with a crystal grating From nine different plates I have found the values given in the accompanying table. The value found by Larsson is Al $K\alpha_1\alpha_2 = 8322\ 48$ X U, or, corrected for the refraction in the crystal, 8321 35 X U The difference $\Delta\lambda$ between the measured values and the crystal determination is given in the second column For every value found for the Al $K\alpha_1\alpha_2$ line I have computed the corresponding value for the electronic charge e.

Al $K\alpha_1\alpha_2$	$\Delta\lambda$	e
8 3405 A	+ 2 3 per thousand	4 807 × 10^{-10} E S U
3406	+ 2 3	807
3399	+ 2 2	806
3410	+ 2 4	808
3373	+ 1 9	802
3406	+ 2 3	807
3393	+ 2 1	805
3397	+ 2 2	806
3423	+ 2 5	811
8 3401	+ 2 25	4 806

As these measurements are based on a direct comparison of X-ray wave-lengths with optical lines of known wave lengths, the values ought to be free from systematic errors The accuracy can be estimated from the different values given in the table The final result is

$$\begin{aligned} \text{Al } K\alpha_1\alpha_2 &= 8\ 340 \pm 0\ 001 \text{ A.} \\ 1{,}000 \text{ X U} &= (1\ 00225 \pm 0\ 0001) \times 10^{-8} \text{ cm.} \\ e &= (4\ 806 \pm 0\ 003) \times 10^{-10} \text{ E S U} \end{aligned}$$

Further details as to the method and the apparatus will be published elsewhere

Significance of Proknocks in Hydrocarbon Combustion

OWING to the complicated nature of hydrocarbon molecules with several carbon atoms, it is difficult to obtain precise evidence as to the nature of the chain mechanisms controlling combustion. Further results have been obtained which throw some light on these processes[1]

A large number of substances have a mild proknock effect as can be measured in knock rating tests; a special class of substances, however, have a pronounced effect in concentrations as low as 10^{-4} and 10^{-6} mol fraction. These organic compounds are so constituted that they can disrupt to give radicals as follows :—

$$C_2H_5O \vdots OC_2H_5 \,;\ C_2H_5O \vdots OH \,;\ AcO \vdots OH,$$

whereas other peroxides, the fissure of which can not take place in this way, show no marked knocking effects; for example —

$$\begin{array}{c} CH_3-C=CH_2 \\ \;\;\;|\;\;\;\;\;| \\ \;\;\;O-O \end{array} \quad \text{and} \quad \begin{array}{c} (CH_3)_2C-CO \\ \;\;\;\;\;\;|\;\;\;\;\;\;| \\ \;\;\;\;\;\;O-O \end{array}$$

Similarly the knocking characteristics of various nitrogen compounds fit in with this, for organic nitrates and nitrites show this same fissure, Steacie[2] has shown that ethyl nitrite decomposes thus, $C_2H_5O \vdots NO$ These compounds have a pronounced proknock effect of the same order as alkyl peroxides Nitro compounds on the other hand, such as nitromethane and nitrobenzene, possess only a slight proknock effect, because fissure does not occur in this manner

These remarks also bear relation to the observations of Hinshelwood, Williams and Wolfenden[3] who show that chain branching in the combustion of hydrogen is due to a similar type of fissure to that discussed above, namely, HO $\vdots$ OH and DO $\vdots$ OD.

Amongst many apparently conflicting phenomena associated with combustion, it would seem that this disruption of an already oxygenated molecule may be common to many *explosion* processes which depend on chain branching The "centres of high energy from which reaction can spread quicker", to which mention was made in some former investigations[4], become the regions where disruption occurs It is interesting to find that the concentrations required for the proknock effect is smaller than 10^{-4}, since concentrations of antiknock of about the same order are required to prevent it

The significance of these and other facts relating to the effect of various substances on knocking and on ignition will be discussed elsewhere

The Thermal Decomposition of Acetaldehyde

NATURE of October 13 and October 27 contain criticisms by Prof M W Travers of work from this laboratory on the thermal decomposition of acetaldehyde. I had already expressed disagreement with similar criticisms at a meeting of the Royal Society in May, and did not wish to enter into a controversy in the columns of NATURE. Lest, however, absence of any comment be interpreted as acceptance, may I be allowed to state quite briefly that fresh experimental work by Dr. Winkler (in process of publication elsewhere) fully confirms that the reaction under the conditions of our previous work is almost entirely homogeneous, and shows by direct chemical analysis that the pressure increase gives a reliable measure of the actual rate of disappearance of acetaldehyde ?

Oxidising Agents and Vat-dyed Cotton

IN the course of an investigation into the action of oxidising agents upon cotton dyed with vat dyestuffs, we have obtained evidence of a simple relationship between the stable potential set up when a platinum electrode is dipped into a dilute solution of sodium hypochlorite, and the amount of chemical modification produced when this solution acts, under standard conditions, upon pure cotton cellulose dyed with the reduced or leuco form of certain vat dyestuffs. These results may prove of interest to those engaged in a study of the chemistry of cellulose and similar polymolecular compounds and also to those who are working on phenomena of oxygen transfer facilitated by a chemically labile substance.

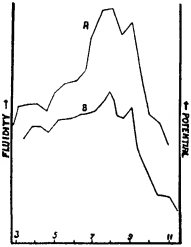

FIG 1.

Certain vat dyestuffs exhibit great resistance to the action of chemical reagents in dilute solution, except that they are readily reduced at the essential quinone groups. The reduction- or leuco-compound is usually unstable, reverting easily to the vat dyestuff on contact with atmospheric oxygen or upon treatment with dilute aqueous solutions of oxidising agents. The presence on the cotton fibre of this reduced form of some vat dyestuffs causes a remarkable acceleration in the rate of chemical modification of the cellulose by dilute sodium hypochlorite. If this modification is measured by the increase in the fluidity (reciprocal of viscosity) of standard solutions of the treated cellulose in solutions of cuprammonium hydroxide, it can be shown that more modification is accomplished in a few seconds in the presence of reduced dyestuff than is brought about over a period of some hours by hypochlorite acting in the presence of the fully oxidised form of the dyestuff, or in the complete absence of vat dyestuff. In all these experiments light is excluded.

In a series of experiments, cotton dyed with a reduced vat dyestuff was treated, in the dark, for 10 minutes with dilute sodium hypochlorite solutions, maintained at a number of different hydrogen ion concentrations by a procedure in which the sodium hypochlorite is employed as its own buffering electrolyte. The connexion between the chemical modification of the cellulose (as measured by its fluidity) and the pH of the hypochlorite solution is given in curve A on Fig. 1. In curve B is shown the connexion between pH of the hypochlorite solution and the potential set up by it at a clean platinum electrode. This potential was measured in the usual way by forming a cell with the platinum electrode and a saturated calomel half element and measuring the E.M.F. of the cell potentiometrically. The potential at the platinum electrode is expressed by comparison with the hydrogen electrode in a solution of the same pH as the solution under examination.

The remarkable agreement between these two curves is not found in the unaccelerated oxidation of cellulose in the absence of reduced vat dyestuff. The agreement appears to indicate (a) simple relationship between the cuprammonium fluidity and the mean molecular size of cellulose modified by accelerated hypochlorite oxidation, (b) a consistent and uncomplicated mechanism for the oxidation of cellulose by hypochlorite over a considerable range of hydrogen ion concentration, when the oxidation is accelerated by reduced vat dyestuff.

The use of reduced vat dyestuffs or analogous accelerating substances may lead to a simplification of the study of the oxidation of cellulose and similar compounds.

A fuller account of this work will appear in a forthcoming issue of the *Journal of the Society of Dyers and Colourists*.

Vision in the Ultra-Violet

IN a letter in NATURE of November 10 (p. 736) Prof. Fabry mentions two publications by Saidman on this subject, hitherto unknown to me, which I

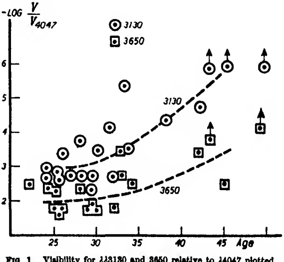

FIG 1. Visibility for λλ3130 and 3650 relative to λ4047 plotted against age. The points marked by arrows mean that the value of $-\log (V/V_{4047})$ is certainly larger than indicated.

read with great interest. In one of them the correlation of the property of seeing ultra-violet light with

age is discussed As I measured quantitatively V_{3650}/V_{4047} and V_{3130}/V_{4047}, it seemed to me of some interest to publish a graph (Fig 1) of these quantities against age, which confirms well that there is a general decrease of visibility between thirty and forty-five years of age, as affirmed by Saidman. Indeed, also in my case no one older than forty-three could perceive light of wave-length 3130

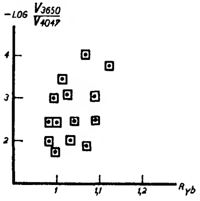

Fig 2 Visibility ratio V_{3650}/V_{4047} plotted against yellow-blue ratio R_{yb} No apparent correlation

The general behaviour of younger and older people was very well confirmed by many tests, which were not worked out quantitatively. I have also tried to plot the quantity V_{3650}/V_{4047} against the yellow-blue ratio. It happened that many of those who underwent the ultra-violet test were measured as to R_{yb} according to Ives (ratio of candle power of specified carbon filament lamp viewed through potassium bichromate and copper sulphate filter) From this graph (Fig. 2), it is seen that this correlation is very poor This emphasises that the question of vision in the ultra-violet is more determined by accidental properties of the eye (colouring of liquids) than by a certain disposition of receptors.

Origin of Variations within Species

IN the salivary glands of the larvæ of *Drosophila*, the chromosomes, which are of immense size, about seventy-five times the length of those in other tissues, show a banded structure. This can be seen in living cells stained with methylene blue and in permanently fixed preparations. The width and spacing of the bands are characteristic and constant for each part of the chromosomes, as was found by Painter[1].

The homologous chromosomes in the salivary glands undergo somatic pairing, hence the number appears to be haploid, each thread actually representing two closely fused chromosomes. This pairing is evidently conditioned by homology in the same way as pachytene pairing. Individuals, heterozygous in respect of the structure of the chromosomes, that is, in the linear arrangement of their genes, show differences of sequence by changes of association.

In *Drosophila pseudo-obscura* there are several geographical lines and races which do not differ in gross morphology, but can be distinguished by the shape and size of the *Y* chromosomes in the males, and by sterility and other abnormalities in their male hybrids (Koller[2], Dobzhansky[3]) La Grande 2 (weak race *A*, Dobzhansky and Boche[4]) and Texas 1 (strong race *A*) are two such races In the salivary glands of the hybrid from the cross between these races, the sex chromosomes pair as in pure races, which indicates complete homology in their internal structure Three out of the four autosomes pair regularly throughout their length, but in the remaining one an intercalary segment of one member pairs in an inverted sense with respect to the segments on either side of it. When pairing is complete, these intercalary segments form a characteristic loop (Fig 1, right) When it is incomplete, either the intercalary segment or one or both of the ends remain unpaired (Fig 1, left). Diagrams of the four possible types of pairing are shown in Fig. 2

(a) (b)

Fig 1 (a) Complete and (b) incomplete pairing of chromosomes in the salivary glands of *Drosophila* carrying inversion.

The cross is therefore a structural hybrid and the two races differ not only in regard to the structure of their *Y* chromosome but also in regard to the structure of one pair of the autosomes. An inversion of a segment has occurred in the history of one of them since their separation from a common stock.

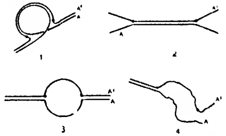

Fig 2 Diagram illustrating the different types of pairing of chromosomes heterozygous for inversion A' indicates the chromosome with an intercalary inverted segment. 1, complete, 2, 3, and 4, incomplete pairing.

Differences in abnormality which occur between males in the crosses involving these races and race *B* cannot be due to the *Y* chromosome alone. There must also be differences between the *X* chromosomes or between the autosomes. In view of these observations, it seems probable that the genetic behaviour is associated with the structural differences found in the autosomes.

Incidentally, it may be noted that it is possible to

analyse variations rapidly by cytological technique, which could only be detected by the experimental breeder with considerable difficulty

Embryo Sac and Embryo of *Moringa oleifera*, Lamk.

This plant was first investigated in 1923 by F L Rutgers[1], who makes some astonishing statements regarding the development of the embryo sac and embryo He states that the archesporial cell is deep-seated in the nucellus, and functions directly as the megaspore mother cell without cutting off any parietal tissue. This on reduction gives rise to a T-shaped tetrad of megaspores of which the lower produces a 5-nucleate embryo sac He further remarks that the fertilised egg undergoes several free nuclear divisions and wall-formation starts only after sixteen nuclei have been formed

As my results are very different from these, I think it worth while to record them briefly

The young nucellus usually shows a single hypodermal archesporial cell This cuts off a primary parietal cell which by further divisions forms three or four wall layers The megaspore mother cell divides in the usual manner to form four megaspores which may either be arranged in a single linear row or in the form of a T

Embryo Sac The nucleus of the functioning megaspore divides three times to form a normal 8 nucleate embryo sac The antipodals are ephemeral, but in some cases they may persist for quite a long period In the former case an older embryo sac would appear to be only 5-nucleate, and it is just possible that Rutgers based his conclusions on the observation of such embryo sacs

In some cases, two embryo sacs were present within the same nucellus, and in one case I saw two paired nucelli each with its separate inner integument, but with a common outer one. Many irregularities exist in connexion with the total number of nuclei in the embryo sac In several cases the egg apparatus was seen to contain four or even five cells. The number of free nuclei in the middle of the embryo sac was found to vary from 2 to 6

Endosperm and Embryo The primary endosperm nucleus divides rapidly forming a mass of nuclei specially crowded at the micropylar end In poorly fixed material some of these nuclei become arranged in such a way that the whole body appears to be a free-nucleate egg A careful study of serial sections reveals, however, that the fertilised egg is situated just above this mass of nuclei and divides much later. The first separating wall is transverse, as in other Angiosperms. The upper cell divides to form a massive suspensor The mature embryo is dicotyledonous, but in some cases it may become tricotyledonous due to a split in one of the cotyledons

I wish to express my sincere thanks to Dr. P Maheshwari for guidance and suggestions throughout the course of this investigation I am also grateful to Prof K Schnarf, of Vienna, who took the trouble of examining some of my slides and confirmed my observations

Structure of the Caudal Fin of the Cod

As the cod is a type commonly dissected by students in zoological laboratories, may I point out an error which still occurs even in the latest text-books concerning the structure of the caudal fin of this fish?

Textbooks assert that there is something peculiar about the tail fin of the cod and other Gadidæ, and state that it is symmetrical both externally and internally. It is also stated that the Gadidæ do not pass through a heterocercal stage in development Hence the fin is described as 'isocercal', 'diphycercal' or 'pseudocercal', and in fact this alleged diphycercy has led to conclusions of great importance such as phylogenetic relationship and the composition of the present fin

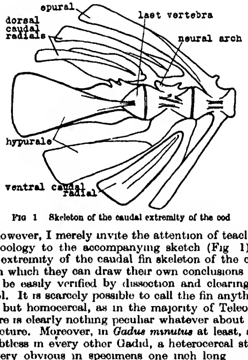

Fig 1 Skeleton of the caudal extremity of the cod

However, I merely invite the attention of teachers of zoology to the accompanying sketch (Fig 1) of the extremity of the caudal fin skeleton of the cod, from which they can draw their own conclusions It can be easily verified by dissection and clearing in xylol. It is scarcely possible to call the fin anything else but homocercal, as in the majority of Teleosts There is clearly nothing peculiar whatever about the structure. Moreover, in *Gadus minutus* at least, and doubtless in every other Gadid, a heterocercal stage is very obvious in specimens one inch long

An exactly similar error appears constantly in regard to the caudal fin of the eel, which is also homocercal For those interested, I venture to direct attention to my previous papers on caudal fin structure in fishes[1]

Estimation of General Ability

IN statistical theory it has been for some time a discipline for statisticians to distinguish by appropriate notation a population parameter that is being estimated and the measure obtained from a sample that is to be its estimate It is now, for example, common for a true population correlation coefficient to be denoted by ρ, and r to be our sample estimate of it

In Spearman's theory of ability there are sufficient real difficulties, without the introduction of one or two of a more artificial kind that I venture to comment on here because they seem to me to have arisen mainly owing to the non recognition of the value of this discipline in the psychological domain If, as a convenient notation in Spearman's two-factor theory, we denote a person's general ability by G, and our estimate of it by g, we can at once realise certain facts about g that have nevertheless been put forward in rather an obscure way in the literature

Thus g will not be identical with G, and consequently it may be said that G is indeterminate A quantity i has been introduced to represent this indeterminacy Though, however, we may choose to write a formal equation relating g, G and i, this will not tell us qualitatively more than we already know, that g in general differs from G The difference may be regarded statistically as the error of estimation, actually it must be a function of the specific abilities corresponding to the tests used This has been pointed out recently by Prof Godfrey Thomson[1]

Further, it has been stated that g is not conserved by linear transformations of the test scores A transformation in general, since it implies that the same test score will contribute to more than one of the new test scores, will introduce group factors where none might have existed before, and correlations among the new test scores will not therefore satisfy the tetrad criterion yet we can always regard any new value g', say, obtained from them as an estimate of G. We shall expect g' to differ from g, but this would appear to have little relevance to what value we ascribe to Spearman's theory

Measuring General Intelligence by Tests which break the *g*-Hierarchy

IN an article in the current number of the *British Journal of Psychology*, I have shown that two tests which fit separately into a hierarchy, but the correlation of which with one another breaks it, can under certain conditions be weighted so as to form a team of two tests correlating perfectly with g The object of the present note is to point out an extension of this principle If k tests each fit separately into a hierarchy, but cannot co-exist in it, their correlations with g ($r_{1g}, r_{2g} \ldots r_{kg}$) can be separately found A team of these k tests can then be formed, with weights proportional to ($-$) the co-factors of r_{1g}, $r_{2g} \ldots r_{kg}$ in the determinant

$$\Delta = \begin{vmatrix} 1 & r_{1g} & r_{2g} & & r_{kg} \\ r_{1g} & 1 & r_{12} & . & r_{1k} \\ r_{2g} & r_{12} & 1 & . & r_{2k} \\ . & . & . & . & . \\ r_{kg} & r_{1k} & r_{2k} & . & 1 \end{vmatrix},$$

to give an estimate of g, and this estimate will correlate perfectly with g if the value of the above determinant is zero If the latter is the case, the k non-conforming tests may be represented as containing among them $k-1$ group components in addition to the general component g

Dipole Moment of Iodine

THE problem of the dipole moment of iodine is of considerable interest. Some years ago, Williams[1] and Muller and Sack[2] measured the moment of iodine in benzene and carbon disulphide solutions and obtained a value of $1\cdot1$–2×10^{-18} c.g.s. units. It is well known, however, that the iodine molecule should have a symmetrical structure It is scarcely likely that iodine would react chemically with benzene under the conditions of their experiments The moment observed was due to some interaction between I_2 and C_6H_6 It seemed strange to us that a moment of the order of magnitude of 1 Debye, that is, a moment characteristic of a molecule of a marked polarity, should arise through the influence of Van der Waals' forces The discrepancy between the value observed and that to be expected from theoretical considerations can be attributed to the imperfection of the method of measurements

The authors mentioned above determined the dielectric constant at one temperature and calculated the moment by subtracting the electronic part, obtained from refraction data, from the total polarisation This method is not sufficiently precise because the atomic polarisation is neglected We have measured the dielectric constant of solutions (1–6 per cent) of iodine in benzene and carbon disulphide at different temperatures from 15° to 70° in the case of benzene and from 15° to 35° for carbon disulphide by the heterodyne beat method

Our experiments show that iodine has no dipole moment in benzene or in carbon disulphide The probable error of our method of investigation is not greater than 0 1 Debye. The electric moment of iodine is, therefore, within the limits of this error, equal to zero

Designation of Logarithms to Base *e*

IN a short review in NATURE of November 3 (p 684) it is remarked that "The notation 'ln' for '$\log_e$' will probably be somewhat strange to British readers".

This notation was used by Jahnke and Emde "Funktionentafeln", and even in the first (1909) edition they did not deem it necessary to explain

the meaning of 'ln', so that it was presumably familiar on the Continent twenty-five years ago; it is also used by Milne-Thomson and Comrie in their "Standard Four Figure Tables" (1931), but they thought it desirable to explain in a conspicuous position that

Logarithms to base 10 are denoted throughout by 'log',
Logarithms to base e are denoted throughout by 'ln',

thus confirming your reviewer's opinion that the notation is "somewhat strange" in Great Britain.

It is to be hoped that this use of 'ln' and 'log' in the latter tables, which are bound to be used more and more as their advantages are recognised, will soon familiarise users with this notation, which appears to possess at least two obvious advantages: it reduces the cost of printing by eliminating the subscript $_e$ or $_{10}$, and it reduces the risk of confusion or error if the hurried user does not notice the subscript.

Large Telescope Mirrors constructed by Dr. J. Peate

IN the years 1895–98 the Rev. Dr. John Peate, of Greenville, Pa., ground and polished a 62 in. diameter telescope mirror for the American University of Washington, D.C. Prior to that time he had made thirteen other reflectors, in the years 1879–95, which are said to have gone to "all parts of the world, including India". The whereabouts of only two of these thirteen mirrors seem to be known, these being at Thiel College, Greenville, and Allegheny College, Meadville, Pa.

I am endeavouring to compile an accurate account of the making of the 62 in. mirror (the largest glass reflector in the world at that time) which was cast in Butler, Pa., in March 1895, and of Peate's activities as a mirror maker generally. May I ask that if any readers of NATURE know the whereabouts of the missing mirrors, and what use has been made of them, they will be so good as to write to me?

F. W. PRESTON.

Box 846,
Butler, Pa., U.S.A.

Points from Foregoing Letters

WHEN the lighter elements are bombarded with slow neutrons, atomic transmutation may occur with release of energy. Dr. J. Chadwick and Mr. M. Goldhaber, by the bombardment of lithium with neutrons from a radon-beryllium source slowed down by passage through paraffin wax, find that helium and triple-weight hydrogen (H^3) are produced, about five million electron volts of energy being released at the same time. Boron gives a similar result, and these elements are therefore indicated as sensitive detectors for slow neutrons.

From the similarity in chemical constitution of certain substances producing cancer and of the female sex hormone, œstrin, it has been inferred that the latter may be able to produce cancer, and some experimental evidence has already been brought to support this view. Prof. J. B. Collip, Dr. H. Selye and Prof. D. L. Thomson now report cancer symptoms in castrated female rats injected with oil-solutions of the sex hormone.

The transformation of radiant energy into 'matter' was deduced theoretically by Dirac, who showed that two units of radiant energy (quanta) may give rise to a pair of positive and negative electrons (having *mass*). Dr. E. J. Williams now calculates the probability of a similar pair being formed from a quantum and an electron within the atom's nucleus (this electron being equivalent to a quantum or photon, from the point of view of an observer approaching it with a velocity nearly that of light).

A discrepancy exists between the charge of the electron computed from the rate of fall of electrified droplets ($4 \cdot 77 \times 10^{-10}$ E.S.U.) and that calculated from the wave-length of X-rays determined by the ruled-grating method ($4 \cdot 80 \times 10^{-10}$ E.S.U.). This would lead to a corresponding difference in the unit used in measuring X-rays, namely, the X-unit (= 0·001 A. or 10^{-11} cm.). This will have to be increased, according to Mr. M. Söderman, by about 0·2 per cent (or the numerical value of the X-ray wave-lengths correspondingly changed).

Messrs. A. R. Ubbelohde and A. Egerton put forward the view that the presence of organic molecules which, when disrupted, give rise to radicals (HO-, C_2H_5O-, etc.), increases the amount of knocking in the internal combustion engine and plays an important part in many explosive processes.

A fairly close parallelism between the electromotive force of a platinum electrode in solutions of hypochlorite and the action of the latter upon cellulose fibres dyed with a reduced vat dyestuff, is reported by Mr. H. A. Turner, Mr. G. M. Nabar and Prof. F. Scholefield. The extent of the action was determined from the change in fluidity observed when the cellulose fibre was dissolved in cuprammonium hydroxide solution.

The order of arrangement of genes (carriers of hereditary traits) along the chromosome threads may give rise to peculiar loops, when chromosomes coming from unlike parents (heterogeneous as regards structure) are paired. Mr. P. Ch. Koller submits photographs and diagrams of such abnormally paired chromosomes in the cells of the salivary gland of the fruit fly (*Drosophila*). He points out that they can help in the rapid determination of variations within a species.

A description of the development of the embryo in the seeds of *Moringa oleifera* (from which oil of ben, similar to olive oil, is extracted) is given by Mr. Vishwambhar Puri. It differs from that given by F. L. Rutgers in 1923.

Prof. C. Spearman postulates that ability is made up of a factor due to training in the particular field under consideration, and another factor due to intelligence or general ability, G. Mr. M. S. Bartlett states that the latter quantity is indeterminate; it differs from the experimentally estimated ability, g, by a factor which depends upon the specific abilities corresponding to the tests used in measuring intelligence.

ERRATUM.—The value of the E.M.F. obtainable from xanthine-uric acid, as obtained by Miss Filitti, was given in this column last week as − 0·113; it should have been + 0·113.

Research Items

Domestic Fowl in Britain. A collection of antiquities from York made by the late William Hewitt of York when excavations were being carried on in High Ousegate in 1903 was acquired by the Municipal Museum, Hull, and has recently been placed on exhibition in the Mortimer Museum. Among the objects in the collection, described with illustrations by Mr. T. Sheppard in the *Naturalist* of December, were twenty-one needles, principally of bone and occasionally of ivory, varying from 5⅜ in. to 2⅜ in. in length. Some of the bone needles are curved and possibly were made from the ulnar bone of a hare. There were also fifteen pins of bone or ivory, varying in length from 4½ in. to 1¼ in. A hollow tube 5¼ in. long may be a comb case. It has a deep groove cut in the centre, as though it had been used as a holder. This, and a smaller tube, are made from a mammal bone. With these objects were two hone-stones or sharpeners, with perforations for hanging, a tine of red deer antler, sawn off and sharpened to a square point and an amber pendant. Of the spindle whorls, one of slate is elaborately decorated with concentric rings on the convex side. There are two massive jet rings and a terra-cotta mask with a face and head-dress almost Egyptian in style. Among the bones of pig, ox, red-deer and horse, were two specimens which are the tibia and femur of the domestic fowl, *Gallus domesticus*. In a recent discussion in the *Ibis* on the domestic fowl in Britain in pre-Roman times, Dr. P. R. Lowe argues, against the previously accepted view, that it was indigenous. These two bones from York would appear to confirm his observation.

Bird Sociology. So many anecdotes have been circulated about the attentiveness of individual birds to others of their kind in difficulties, that a light on the other side of bird relationships should not be out of place. Eric C. Kinsey has studied in California the habits of the long-tailed yellow-breasted chat (*Icteria virens longicauda*). He trapped the female of a pair, and on the following day the male appeared with a new mate and immediately started nesting operations within a few feet of the old nest, notwithstanding the fact that his old mate was anxiously calling to him from a trap placed alongside the old nesting site. He appeared to be indifferent to her presence in the immediate neighbourhood and entirely heedless of her difficulty. Indeed, it was found to be a rule for this species that a captured individual, male or female, of a pair, never succeeded in decoying its mate into the same trap. Mating seemed to be casual: of another pair, the male was first trapped, two days later the female appeared with a new mate, whereupon she was trapped, and on the following day the same male appeared with a new female (*Condor*, 36, 235; 1934). The regardlessness and fickleness of this chat is in marked contrast to the habits of some other passerine birds which are devoted mates.

Indian Leafhoppers or Jassidæ. Dr. H. S. Pruthi has published a second contribution to the above subject (*Mem. Indian Mus.*, 11, No. 2, July 1934). In the present work he describes the genotypes of some of the genera erected by the late Mr. W. L. Distant, and also revises the genus *Moonia*, Dist. Dr. Pruthi remarks that Mr. Distant is the author of more than 60 per cent of the genera and species of the family described from India. Unfortunately, both the descriptions and illustrations of most of the new forms described by this author are very inadequate. The need has consequently arisen for a thorough revision and redescription of most of Distant's material in order that progress may be made in the further study of the Indian forms. The present work is a contribution towards that end, and Dr. Pruthi's careful figures, especially of the male genitalia, together with the insect species portrayed on the accompanying plates, should prove of definite value to students of the family in question. The Indian species of Jassidæ, it might be added, constitute an important component of the Jassid fauna of the world, and these memoirs will interest specialists in this large and rather neglected group of insects.

Results of Nerve Grafting. Sir Charles Ballance has recently published a short monograph ("The Conduct and Fate of the Peripheral Segment of a Divided Nerve in the Cervical Region when united by Suture to the Central Segment of another Divided Nerve". London: Macmillan and Co., Ltd., 1934. 7s. 6d. net) dealing with his more recent work on nerve grafting. He finds that when the cervical sympathetic trunk is made to supply a voluntary muscle, the motor end plates have the normal structure and the sympathetic fibres increase in diameter as the end plate is approached. According to Langley and Anderson, it is only the preganglionic fibres of the sympathetic system which can be made to supply voluntary muscle; the post-ganglionic can never take the place of somatic fibres. This distinction agrees with the modern pharmacological grouping of nerve fibres for (in Dale's terminology) the somatic and preganglionic fibres are 'cholinergic' whilst the post-ganglionic fibres are 'adrenergic'. There are, it is true, considerable differences both in the structure and speed of reaction of somatic and preganglionic fibres, but Ballance's work shows that after the substitution has been made, the preganglionic fibres retain their characteristic size in the nerve trunk down which they have grown, but become modified in the muscle as they approach their destination in the motor end plate.

Elm Disease in Great Britain. A brief memorandum issued by the Forestry Commission gives a review of the seventh annual survey of the extent of the attack of the insidious and at times highly virulent malady of the elm genus. During last summer, the disease is said to have made definite progress in nearly every area examined, but the severity of the attack is below the peak year of 1931. Infected trees have been recorded in three new counties, Lancashire, Merionethshire and Cornwall. The classification of the counties of England and Wales shows nine where the attack is frequent and often serious, sixteen where it is sporadic, sixteen seldom found and eleven in which the disease has not yet been reported. It is considered that a more wide-spread survey would almost certainly add to the numbers in the classes 'sporadic' and 'seldom found'. The nine counties where the pest is worst all lie to

the north and east of London, save the Isle of Wight It is said that there is no indication as yet of the disease extending westwards The point of interest which is being studied is what proportion of attacked trees recover partially, but still remain in a condition where the infestation may restart, and what proportion recover entirely In a case in Kent, known to the writer, three young vigorously growing trees, two standing within ten yards of one another, the third a hundred yards away, were attacked some four or five years ago Of the two standing close together the first attacked appeared to have recovered and then died within a year The second has entirely recovered The third tree lost its leader, then died rapidly from the top, and was then felled and burnt The fungus had penetrated into some of the branches half way down the stem The elm bark beetle is said to be a chief carrier of the disease No beetles or their galleries were found in any of the three trees No definite record of the elm disease has yet been reported from Scotland

Specific Heats of Gases at High Temperatures G G Sherratt and Ezer Griffiths, working at the National Physical Laboratory, have measured the specific heat of carbon monoxide at temperatures of the order 2,000° C, using the velocity of sound measured in a graphite tube (*Proc Roy. Soc*, Nov. 15, 1934) Previous attempts to measure the specific heats of gases at high temperatures have been made by the explosion method, involving great experimental difficulties and large uncertain corrections. The train of sound waves was set up by a quartz piezo-electric crystal, the effective length of the tube was varied by moving a carbon piston, and the condition of resonance was indicated by changes in the plate current of the oscillator maintaining the vibration of the quartz crystal Temperatures were measured by a disappearing filament pyrometer Since the velocity of sound in a gas shows a dispersion effect, being different for different frequencies, the velocity was measured at several frequencies and a correction applied, using a theoretical result of Kneser The specific heat finally deduced was in good agreement with that deduced from band spectroscopic data

Molecular Clustering in Fluids R S. Krishnan (*Proc Indian Acad Sci*, Oct. 1934) has made optical experiments to test for the presence of molecular aggregates in liquids and liquid mixtures A beam of polarised light was passed through the liquid, and the 'depolarisation' (that is, the ratio of the intensity of the horizontal to the vertical components of polarisation) of the light scattered at right angles is observed If the scattering particles are comparable in size with the wave length of light, this depolarisation may be observed Negative results were obtained with a number of organic liquids Positive results were obtained with a binary liquid mixture (carbon disulphide + methyl alcohol) and this effect persisted at temperatures lying within a considerable range around the critical solution temperature

Exploration of the Upper Atmosphere by Self-Recording Balloons. E Regener and his co-workers (*Phys Z.*, Oct. 1, 1934) have obtained further information on cosmic rays and on the absorption of light in the atmosphere by the use of beautiful self-recording instruments carried by sounding balloons E Regener and G. Pfotzer sent up a Geiger-Müller counter, which with its high-tension battery and counting mechanism gave a load for the balloon of about 6 kgm The apparatus attained a height of 28 km and the impulses counted gave a variation with height practically identical with that formerly observed with ionisation chambers The readings at the highest altitudes show a transition effect due to the formation of secondary radiations as the radiation enters the atmosphere Measurements were made by E Regener and R Auer with a large, open ionisation chamber connected to a self-recording electrometer, the chamber being in some experiments lined with paraffin or celluloid The experiments showed that no large part of the cosmic ray intensity was due to neutrons E Regener and V H Regener sent a quartz spectrograph to a height of 30 km with a balloon In order to avoid setting the spectrograph to point at the sun, the slit was directed towards a white disc illuminated by the sunlight The camera took a number of spectrograms on a rotating plate, the height being indicated on each by the shadow of an aneroid pointer The plates were measured in a photometer at two different wave lengths lying in the region where the absorption of ozone sets steeply in, and the results used to obtain the distribution of ozone in the atmosphere. The maximum concentration of ozone appears to lie in the region 24 km high, and at 30 km height 70 per cent of the ozone lies below the apparatus. This result agrees with the estimates of Goetz, Meetham and Dobson, rather than with the earlier view that an ozone layer existed at 40–50 km. height

Activity Coefficients of Sulphuric Acid. Most of the measurements of the activity coefficients of sulphuric acid have been made with the Hg/Hg_2SO_4 type of electrode The solubility of mercurous sulphate, however, prohibits its use in acid concentrations below 0 005 molal The cell containing two-phase lead amalgam, with lead sulphate as depolariser, is free from this objection and has been used by J Shrawder and I. A Cowperthwaite (*J Amer. Chem Soc*, **56**, 2340, 1934) in measurements of the activity coefficients of sulphuric acid from 0° to 50° over the concentration range 0 02 to 0 001 *m*. The calculations are somewhat difficult, since the degree of ionisation of the acid, involving the two ions HSO_4' and SO_4'', has to be taken into account, and some assumptions are required. The results at 25° are compared with the La Mer, Gronwall and Greiff extension of the Debye-Huckel theory on the assumption of an ionic size of 1 75 A. The results are also applied to the calculation of the heats of dilution of sulphuric acid. The results are widely divergent from those obtained by the calorimetric method, particularly at low concentrations. When plotted against the square root of the molality, the calorimetric heats of dilution provide a curve which becomes linear below 0·001 *m*. The electro chemical values indicate a curve which exhibits a point of inflexion such as would be required to bring the curve into the limiting Debye-Hückel slope. A large part of the difference is shown to be due to the different methods of extrapolation used, and adequate agreement is obtained above 0 0036 *m*. The calorimetric data are, however, shown to be in disagreement with several independent results of electromotive force measurements, so that there is at present a real discrepancy between the values of the heat of dilution determined by the two methods which is not explained.

Experimental Work on Cancer

IN the recently issued annual report of the Imperial Cancer Research Fund[1], Dr. J. A. Murray records the main properties of twenty-eight different strains of animal tumours which are maintained in the laboratories of the Imperial Cancer Research Fund. He appeals to other institutes to publish similar "statements of the significant characteristics of the tumour strains maintained by them so that investigators throughout the world may more easily compare their material and results".

Rous and Murphy showed that fowl tumours transmissible by cell-free material retain their individual properties, in appearance, rate of growth and distribution of secondary tumours. In the first paper of the scientific report[2], Dr. Foulds describes such characteristics for six different chicken tumours, and concludes that the behaviour of these tumours is parallel to that of metastases in human cancer. In a supplement to the report[3], Dr. Foulds gives a detailed summary of the work on the properties of the filtrates which produce tumours in fowls and on the characteristics of such growths. The specificity of the malignant tissue produced by filterable agents and the multiplication of such agents with the growth of the tumour differentiates them from the chemical carcinogenic agents. On the other hand, the 'organisers' induce embryonic structures, the growth of which then appears to increase the amount of organiser.

The fourth and fifth papers of the report deal with investigations carried out by Dr. A. F. Watson on the effect of liver diet on tar cancer. Maisin showed that when either fresh or cooked liver was fed to mice, they became more susceptible to painting with carcinogenic tar. Watson has shown that a preparation of hog's stomach containing the hæmopoietic factor did not have the same effect as liver. The results of liver feeding show that the mortality of the control mice is much higher than that of the liver-fed animals; this effect seems to be greater than the influence on tumour production.

Dr. E. S. Horning has developed a technique by means of which the distribution of inorganic matter in tissues can be studied. The fixed and sectioned tissue is heated to 650° C., after which the distribution of the ash can be seen by means of dark-ground illumination. From this, the form and character of the original cells can be seen. Hypertrophied stroma and most malignant cells appear to contain more inorganic matter than normal cells; in this respect, however, tar tumours seem to differ from other tumours. The method has shown that radium treatment causes redistribution of the inorganic matter; changes are shown within six hours of irradiation and continue for six days. There seems no doubt that micro-incineration is a valuable histological and chemical method.

Mr. H. G. Crabtree and Dr. W. Cramer show that treatment of transplantable tumour tissue with the maximum concentration of poisons producing reversible inhibition of the respiration will also allow the tissue to grow when implanted in a host. If the poison is used in a higher concentration, the tissue will not grow on transplanting. They also show that the physiological environment affects the susceptibility to radium; in general, lowered respiration causes increased susceptibility. Dr. Cramer has been able to demonstrate that the differences in sensitivity to radium of spontaneous mammary carcinomata in mice are partly due to variations in the extent of macrophage invasion. He points out that effective radiation need not kill all the cells directly, but only cause temporary but specific damage.

The last two papers of the report are by Dr. R. J. Ludford and deal with the structure and behaviour of cells in tissue cultures of tumours. Macrophages, polyblasts, lymphocytes, giant cells, fibroblasts and malignant cells, all of which occur in such cultures, are described. Apart from their morphology, the cells can be differentiated by their movements and reactions to vital stains. Careful subculture has given almost pure cultures of malignant cells. Ludford has been able to use colloidal solutions of fat-soluble dyes as a vital stain for the fatty parts of cells. All cells are stained by such dyes, but as malignant cells are not stained by the water-soluble trypan blue, it is suggested that the plasma membrane of malignant cells is relatively rich in fatty substances. In this respect, the membrane resembles that of the tubercle bacillus.

Many of the papers are fully and beautifully illustrated, and the descriptions immediately below the plates themselves are a great help to the reader.

Annual Meeting of the Science Masters Association

THE thirty-fifth annual meeting of the Science Masters Association was held on January 1–4 at Oxford under the presidency of Prof. N. V. Sidgwick. Some three hundred members were present, a number slightly less than the usual number for an Oxford meeting, although the membership of the Association has risen to within the region of two thousand.

A full programme of lectures, visits and demonstrations was arranged, together with the usual exhibits by manufacturers and publishers. Various departments of the University were open for inspection and special demonstrations were staged, particularly in the Astronomical, Biochemical, Botanical, Electrical and Chemical Departments.

The presidential address, under the title of "Real Molecules", was a lucid account of the modern physical conceptions of atoms and molecules developed as the result of the applications of the ideas of wave mechanics, which, in the opinion of Prof. Sidgwick, affect only to a slight degree the dimensions of atoms and their orbits as deduced from the classical theory, but give a much clearer conception of the mechanism of covalency. By assigning to every nucleus a sphere of influence, the dimensions

of which can be ascertained by X-ray methods and spectroscopy, and by defining the size of an atom as that portion of space into which other atoms cannot enter, it is possible to avoid the difficulty created by wave mechanics of a cloud of electrons of indefinite size surrounding the nucleus. Using this conception of the size of atoms, combined with a knowledge of the angles between the valencies, a molecular model can be built up This model, however, has a volume much less than the molecular volume obtained in other ways Hence it becomes necessary to assume the existence of an envelope (due to the electrostatic repulsion of the electrons of different atoms within the molecule) surrounding an atom in combination, the thickness of the envelope being dependent on the various types of linkage The effects of molecular collisions on molecular change were also discussed, with particular reference to the possibilities of twisting component parts of the molecules round the valency bonds, the compression and rarefaction of the bonds, and the alteration of their angular values

Mr C N Hinshelwood gave a lecture on "Some Aspects of Modern Physical Chemistry", discussing the significance to chemistry of quantum mechanics, which, he said, has added new laws and methods of calculation in physical chemistry without disturbing existing laws to any great extent Zero point energy, chain reactions, structure of liquids, and heavy hydrogen were topics included in this survey

An evening lecture was given by Prof H H Plaskett on the "Physics of Astronomical Vacua", with special reference to the density and source of luminosity of gaseous nebulæ The lecture was followed by an inspection of the University Observatory "The New Aspect of the Elementary Theory of Organic Chemistry" was taken by Prof R. Robinson as the subject of another evening lecture, in which, using the conception of anionoid and cationoid reagents, he showed how the electron theory is resulting in a unification of physics and organic chemistry Other lectures were "Plant Respiration" by Dr W O James, "Ionisation by Collision" by Prof J S E Townsend, "Tissue Respiration" by Mr R B Fisher All these lectures were much appreciated by members of the Association, for whom much of the value of these annual meetings lies in the lucid résumés of modern work by experts in their various subjects.

A lecture-demonstration which attracted much attention was given by Dr K J Franklin on "X ray Cinematography" This was illustrated by films of the circulation of the blood and respiratory movements of various mammals

Sound film demonstrations formed a large and interesting part of the general programme of the annual meeting Three films were shown, suggested as suitable films for class science teaching by the British Film Institute, on which body the Science Masters Association has representatives The films were "The Molecular Theory of Matter", "Sound and its Production", and "The Cathode Ray Oscillograph" While all these films did not find favour in every particular (indeed humour was provoked in unexpected places), it was realised that here is a valuable addition to teaching technique, particularly as a method of revision Difficulties in the matter of cost, standard projectors, silent versus talking films, were raised and discussed at the demonstrations

At the business meeting, the following elections took place *President*, Sir William Bragg, *Secretary*, S V Brown (Liverpool Institute); *Annual Meeting Secretary*, R E Williams (Repton), *New Committee Members*, Dr W G Davis (Newcastle Grammar School), L G Smith (Marylebone Grammar School), F R Snell (Eastbourne College). Changes were made in the rules to permit of the election of honorary members, and all past presidents were elected to that dignity. The annual report showed that the Association has now 1921 members representing 797 schools, an increase in the year of 109 members and 40 schools The branch organisation of the Association is proceeding apace The North Eastern, South Wales and North Western branches have been in existence for several years. Other branches in Yorkshire, East Anglia and possibly Middlesex are in process of formation This branch organisation, it is realised, is likely to involve difficulties of representation

The annual meeting for 1936 will be held in London under the presidency of Sir William Bragg

Periodic Variations in the Mean Focal Depth of Japanese Earthquakes

By Dr. Charles Davison

DURING the last ten years, many estimates have been made of the focal depths of earthquakes in Japan They depend on the duration of the preliminary tremors at three or more neighbouring stations Two lists have been published, one by Mr. N. Nasu of the after-shocks of the Tango earthquake of March 7, 1927 (*Earthq. Res Inst Bull*, 6, 245–331; 7, 133–152; 1929), the other of ordinary earthquakes felt in Tokyo from 1924 onwards, now issued quarterly by the Earthquake Research Institute

After-Shocks of the Tango Earthquake of 1927 —Mr. Nasu has determined the position of the epicentre and the depth of the focus of 482 shocks from March 11, 1927, to July 16, 1928. The values obtained for the depths range from 0 to 44 km, the mean of all being 15 4 km. or, excluding zero estimates, 15 9 km. The after-shocks are subject to several well-marked periods—of one day, 29 6, 14 8 and 7 4 days, and 42 minutes.

From March 14 to August 31, the focal depths of 438 after-shocks are given The maximum epoch of the diurnal period in the frequency of these shocks occurs at 3 a m., the amplitude of the period being 0 24 During the same interval, the mean depth of the foci was 14 9 km, and the mean depth during successive hours is also subject to a diurnal period with its maximum at 3 a m. and its amplitude 0 03, that is, the oscillations in mean depth due to this period range within about 0 45 km of the mean

The lunar periods are more clearly marked During the 16 lunations from April 2, 1927, to July 17, 1928, the depths of 247 foci were estimated, the mean of all being 16 7 km For both frequency and mean depth, the maximum epoch of the 29 6 day period falls not far from the time of full moon, the amplitudes being 0 37 and 0 09; the epochs of the 14 8 day period fall close to the times of first and last quarters, with amplitudes of 0 39 and 0 09, and those

of the 7·4 day period about the times of the four principal phases, with amplitudes of 0·16 and 0·11 The ranges about the mean depth for the three periods are, respectively, 1·50, 1·50 and 1·84 km

The 42-minute period affects both the frequency and the mean focal depth of the Tango after-shocks until the end of May During March and April, the minima of the periods for both frequency and depth coincided approximately with the return movements from the antipodes of the focus, the amplitudes being 0·25 and 0·06 in March and 0·33 and 0·10 in April, while, in May, the maxima coincided closely with those returns, with amplitudes of 0·54 and 0·13 The ranges about the mean depth during the three months are, respectively, 0·97, 1·64 and 1·91 km

Ordinary Earthquakes felt in Tokyo—The lists of such earthquakes, with their estimated focal depths, are given from 1924 to 1933 In the results that follow the earthquakes for the year 1924 are omitted on account of the unusually large number felt in January of that year Of 564 shocks felt during the remaining nine years, the focal depths of 388 are determined The variations in mean depth show periods of one year, one day, and 14·8 and 7·4 days

The maximum epoch of the annual period in the frequency of the earthquakes occurs at about the end of March, the amplitude being 0·11. The mean focal depth of the earthquakes is 46·7 km., and the maximum epoch of the variations in monthly mean depth occurs in the middle of March, the amplitude being 0·08, that is, the range on either side of the mean is 3·7 km

The diurnal period in the variation of mean focal depth is less pronounced For the same earthquakes, the maximum epoch of the variation in frequency occurs at 2 a.m., the amplitude being 0·28 The maximum epoch for the mean focal depth occurs at about 11 p.m., the amplitude being 0·05, that is, the range of variations about the mean is 2·3 km.

For the lunar periods, the number of earthquakes of known focal depth from January 25, 1925, to December 17, 1933, is 372. For both frequency and depth, the maximum epochs of the 14·8 day period fall near the times of new and full moon, the amplitudes being 0·16 and 0·03, and the range on either side of the mean depth 1·4 km. The epochs of the 7·4 day period fall near the times of the four principal phases, the amplitudes being 0·14 and 0·04, and the range on either side of the mean depth 1·9 km.

University and Educational Intelligence

CAMBRIDGE.—The Adam Smith Prize offered annually for an essay on some unsettled question in economic science or in some branch of economic history or statistics subsequent to the year 1800 selected by the candidate himself has been awarded to Mr. W. B. Reddaway, of Oundle and King's College, who was placed alone in Division I, Class I, in Part II of the Economics Tripos last June. The prize is valued at £40.

The governing body of Emmanuel College invites applications for a research studentship which will be awarded in July 1935. Preference will be given to candidates who have already completed one but not more than two years of research. The studentship has a maximum annual value of £150, and is awarded and normally held for two years. The studentship is not open to a woman or to a graduate of the University. Further information can be obtained from the Master, Emmanuel College, Cambridge.

ST. ANDREWS.—R. A. Smith has been appointed Carnegie teaching fellow and assistant in applied mathematics in the United College, St. Andrews, in succession to Dr. D. E. Rutherford, who has been promoted to the post of lecturer in mathematics and applied mathematics.

PROF. F. E. WEISS, formerly Harrison professor of botany in the University of Manchester, has been appointed to take charge of the botanical department of the Egyptian University at Abbassia, Cairo, from February 1 until the end of May, in succession to Prof. F. W. Oliver, who is retiring from the professorship

Science News a Century Ago

Faraday's Eyesight

Faraday's "Diary" is strictly a laboratory record of experiments, and from end to end there are very few references in it to matters outside his experimental work One of these personal entries occurs on January 15, 1835

"Within the last week have observed twice that a slight obscurity of the sight of my left eye has happened It occurred in reading the letters of a book, held about 14 inches from the eye, being obscured as by a fog over a space about half an inch in diameter This space was a little to the right and below the axis of the eye Looking for the effect now and other times, I cannot perceive it. I note this down that I may hereafter trace the progress of the effect if it increases or becomes more common."

It does not seem that the obscurity occurred at all frequently, for no further reference to it in the "Diary" has been traced. None of Faraday's biographers makes any reference to defective eyesight The thick glass spectacles used by him, which are preserved at the Royal Institution, were worn only to protect his eyes from the effects of explosions during the experiments on the liquefaction of gases Among the numerous portraits of him one photograph has been found, taken probably after 1860, in which he is holding a pair of spectacles in his hand; and it would appear that he used glasses for reading in his later years; but apart from this, it is evident that he retained his sight practically unimpaired to the end

Geographical Exploration

On January 15, 1835, *The Times* said: "A lecture interesting both to the friends of science and the friends of commerce was last night delivered at the London University by Captain Maconochie. The lecturer commenced by saying two expeditions of discovery were now being sent out by the efforts of the Royal Geographical Society. One of these expeditions was to explore the interior of Southern Africa and the other to explore the regions to the south and south-west of British Guiana. The Geographical Society had done much to further discovery and their exertions had been most beneficial to the promotion of geographical science." Referring to the expedition to Africa, Capt. Maconochie said: "The continent of Africa had already been penetrated 1,400 miles from the Cape of Good Hope The countries further north were found to be the furthest advanced in the arts of civilised life. At the distance

of 1,400 miles from the Cape the arts of smelting iron and copper, and of carving in ivory were known Commerce had penetrated in that direction nearly 1,400 miles, and a trade to the amount of 1,600£ had been carried on in one expedition Captain Alexander had volunteered to explore these regions. He had sailed from England in September last " As regards the expedition in British Guiana "The French nation had sent out two gentlemen for the purpose of making discoveries, and from the funds of the Geographical Society 500£ had been given towards sending out from this country a gentleman for the same purpose The Government of the country had contributed 1,000£ to forward his exertions in so laudable an enterprise "

The Eastern Counties Railway

By 1835, plans for railways to connect London with the north, south, west and east of England were being prepared, and on January 17, 1835, the *Mechanics' Magazine* said that the "Eastern Counties Railway which is to run from London to Yarmouth, by way of Chelmsford, Colchester, Ipswich and Norwich will be one of the most level, for its length, yet laid down in the whole kingdom According to the report of the engineers, there will be nowhere a greater rise than 1 in 400, no embankment of more than 28 feet high, and not a single tunnel throughout its whole length The average cost per mile will, in consequence of these singularly favourable circumstances, be less than any other railway constructed, or in progress of construction, in Great Britain The estimates of revenue are also extremely encouraging From there being no canal communication between the metropolis and the counties of Essex, Suffolk and Norfolk, there is a greater waggon traffic on this line than on any other in the kingdom The passenger traffic is also so considerable, that it would of itself suffice to pay all the expenses of the railway, and leave a handsome profit to the proprietary "

Volcanoes of South America

On January 18, 1835, for the second time, H M S *Beagle* anchored in the bay of San Carlos in Chiloe "On the night of the 19th," wrote Darwin, "the volcano of Osorno was in action At midnight the sentry observed something like a large star, which gradually increased in size till about three o'clock, when it presented a very magnificent spectacle I was surprised at hearing afterwards that Aconcagua in Chile, 480 miles northwards, was in action on this same night, and still more surprised to hear that the great eruption of Coseguina (2,700 miles north of Aconcagua), accompanied by an earthquake felt over a 1,000 miles, also occurred within six hours of this same time This coincidence is the more remarkable, as Coseguina had been dormant for twenty six years; and Aconcagua most rarely shows any signs of action It is difficult even to conjecture, whether this coincidence was accidental, or shows some subterranean connection. If Vesuvius, Etna, and Hecla in Iceland (all three relatively nearer each other than the corresponding points in South America) suddenly burst forth in eruption on the same night, the coincidence would be thought remarkable, but it is far more remarkable in this case, where the three vents fall on the same great mountain-chain, and where the vast plains along the entire eastern coast, and the upraised recent shells along more than 2,000 miles on the western coast, show in how equable and connected a manner the elevatory forces have acted "

Societies and Academies

Dublin

Royal Dublin Society, November 27 E J SHEEHY. A crate for the collection of fæces and urine adjustable for metabolism experiments (solid and liquid) with pigs, sheep and cattle of various sizes J HARDIMAN, J KEANE and T J NOLAN The chemical constituents of lichens found in Ireland *Lecanora gangaleoides* (1) This lichen contains, besides chlor-atranorin, a chlorinated depsidone of constitution $C_{16}H_9O_5Cl_3(OCH_3)_2$ closely allied in structure to diploicin, $C_{16}H_7O_4Cl_4(OCH_3)$, previously found in the lichen *Buellia canescens* H H POOLE and W R G ATKINS The measurement of the current generated by rectifier photo-cells A modification of the method recently described by Campbell and Freeth has proved very suitable for photometric measurements over a very wide range of illumination, and is especially adaptable to marine work (see NATURE, Nov 24, p 810) THOMAS DILLON and TADHG O'TUAMA. The cellulose of marine algæ. Cellulose was obtained from species of *Laminaria* (1) by successive extraction with ammonia and with caustic soda and (2) by a process of retting followed by extraction with soda The methyl and acetyl derivatives and the thiocarbonate of this cellulose resembled in properties the corresponding derivatives of the cellulose obtained from land plants When the cellulose was hydrolysed with sulphuric acid, glucose was obtained, which was identified by the osazone Failure to obtain glucose from algic cellulose reported by other authors may have been due to the impurity of the cellulose, which in the plant appears to be closely associated with a substance corresponding to the lignin of land plants VINCENT BARRY and THOMAS DILLON Preparation and properties of alginic acid and the extraction of marine algæ with various solvents High viscosity has always been regarded as the most characteristic property of solutions of the alkali alginates It has now been found that, if the fronds of *Laminaria digitata* are extracted with boiling water and then with ammonia, the ammoniacal solution which contains the alginic acid is not highly viscous, and filters easily Extraction with a series of solvents in the order mentioned gave approximately the following extracts expressed in percentages of the dry plant: water 40, industrial alcohol 10, industrial alcohol containing a little hydrochloric acid 2, ammonia 20, boiling caustic soda 20, residue of cellulose 8.

Individuality in Industry

ATTENTION has frequently been directed in recent years to the growth of the professional spirit among those responsible for the control and organisation of industry, whether on its financial, commercial or technical side Mr C H Bailey was not therefore breaking fresh ground in stressing this point in a recent stimulating address to the Birmingham and District Association of the Institution of Civil Engineers Already industry is being regarded as a public service—it is judged less by its capacity for earning profits than by the service it renders to the community to a much greater extent than formerly, Sir Josiah Stamp's reference to the service and profit motives in industry at the British Association meeting in Aberdeen was a warning against hasty conclusions as to the adequacy of the service motive alone, rather than a dissension from this view of the importance of industry

The professional ideal of fitness for a purpose which is implicit in technology makes the professional contribution to industrial efficiency all-important in these days In the address to which we have alluded, however, Mr Bailey proceeded to show how professional institutions, in providing a standard of professional conduct and skill for those engaged in the technical direction of industry, cannot fail to be concerned with the changes in the structure of industry and society which are taking place through mechanisation. It is not merely that the professional spirit requires them to consider the type and size of the industrial unit or organisation which can serve most efficiently the needs of industry and the community They must also consider such questions in relation to the well-being of members of their own profession and of society as a whole

Loyalty to the highest professional ideals involves the consideration of these larger social questions If machines, for example, can be used most efficiently, from the mechanical point of view, in large concentrations, the professional man must also consider the consequences of such concentration on individual incentives and initiative If such concentration seriously limits the opportunities for the expression of individuality and destroys incentives by removing many of the opportunities for rising sooner rather than later to a position of free responsibility, the depressing effect on the quality of industrial recruits must

soon or later be seriously reflected in the efficiency of the industry.

The gravity of the check to the mobility of industrial labour, which has been imposed alike by the mechanisation of industry and by changing educational conditions, is as yet not generally realised, although it has been emphasised in recent discussions on technical recruitment for the cotton industry The importance of adequate incentives in large-scale industry was, however, a main theme in the important address delivered by M H Dubreuil before the Department of Industrial Co-operation of Section F (Economic Science and Statistics) at the Aberdeen meeting of the British Association, and it strongly supports the contention that the essential problem is to organise mechanical manufacture in such a way that it affords more men the opportunity of using their capacities to the fullest extent. Mr Bailey's suggestion that industry should perhaps be organised more in small units in which more men could look forward to occupying positions of real responsibility, is not so much an attack on the size of industrial undertakings, or a pessimistic assertion of limits to the organising capacity of the human mind, as a reminder that, in the long run, industrial efficiency cannot be dissociated from social efficiency, and as such deserves careful consideration

The problem of securing free play for individuality is as vital to industrial success as it is in scientific research or other activities Without it, team work is apt to degenerate into something mechanical in which creative ability and original thought languish Management, in fact, consists in taking care of the fundamental principles of organisation which implicitly respect the individual, and applying them to the purposes of the undertaking, and such principles have nothing to do with the size of the undertaking J M Scott's tribute to Watkins's knack of making everyone a 'boss of something', and so allowing him to feel a personal glow of pride in every achievement, is not more an explanation of the success of an expedition of three men and a team of dogs in the heart of Labrador than it is the secret of successful management in the largest industrial organisations that exist

M. Dubreuil's paper on autonomous groups in industry is of interest in this connexion, as indicating how wide a research field management still presents in just this matter of delegating responsibilities and associating the workers with the success of the undertaking in which they are employed In such research the professional spirit as well as scientific method must play its part, and while even from the narrowest professional point of view any institution such as the Institute of Chemistry or the Institution of Civil Engineers must recognise a real responsibility to its younger members to ensure that they have opportunities of utilising fully their ability, that responsibility is most wisely discharged when it is seen as part of the wider social and industrial responsibilities of the profession

Discussions on the decline in the number of students attending technical courses of training for the cotton industry have once more emphasised the necessity for each great industry to consider both the quantity and the quality of its recruits Unless an industry can make up its mind what numbers of recruits it needs, from what types and grades of schools or institutions they should be drawn, and in what proportion, and couples with this an adequate system of training and promotion, there is grave danger that the industry will find itself without a supply of recruits of the requisite calibre, or at least with such an insufficient supply that its efficiency is seriously affected and its power of expansion or recovery is impaired

The extent of juvenile unemployment and the situation revealed by the reports on the depressed areas in the Midlands and North of England may easily engender a false confidence in industry at the present time No industry can afford to recruit continuously, whether in its lower or its higher ranks, from those whose morale has been undermined by continuous exposure to intermittent or blind-alley employment and who are, in desperation, prepared to accept any situation which offers the prospect of steady work irrespective of their capacity. Nor can any industry ignore indefinitely the value of a planned policy of recruitment, training and promotion as a means of attaining the efficiency which enables it to hold its own in days of severe and unremitting international co-operation.

The question of industrial training and recruitment is thus one which is forced upon the attention of professional men in industry in many ways Loyalty to their own junior colleagues demands its consideration. Their responsibilities as managers lead them to the study of new methods for securing the continuous co-operation of members of their staff and developing the morale and team spirit which are essential to efficiency and success.

Finally, the social responsibilities of industry demand the study of industrial structure and organisation, recruitment, location and planning of industries, so as to serve those general interests of the community with which ultimately the interests of industry are inseparably linked It is when these problems are approached from the point of view of life as a whole, and not merely of production, that the professional workers will succeed in making the contribution to industrial efficiency and social welfare which the community has a right to expect

Reviews

Philosophy in the Garden

The Genetics of Garden Plants By M B Crane and W J C Lawrence Pp xvi+236 (London Macmillan and Co, Ltd, 1934) 10*s* 6*d* net

THE occupation of gardening is both ancient and honourable, though it is only in comparatively recent times that those engaged in it have paid much attention to the origin of the material with which they work Whether for utility, for medicinal use or for sheer beauty, European gardeners in older days were content to grow the plants that they found to hand, adding to them such new things as were brought in by the voyagers gradually exploring the world. To their enthusiasm and energy the works of the herbalists bear witness But while these noble compilations were in progress a new era in horticulture was dawning The discovery of the nature of sex in plants, initiated by Camerarius and so ably followed up by Kolreuter, led to the organised production of novelties through the method of hybridisation

The great burst of work of this kind throughout the nineteenth century, so closely associated with the names of Knight, Herbert and Laxton in Great Britain, and of Louis Vilmorin in France, led to a vast enrichment of the flower and vegetable borders as well as of the orchard Meanwhile, the philosopher had wandered out of his study into the garden Developments so notable had begun to attract his attention, to challenge him to fit them into his scheme of things The challenge was taken up, and philosophy's very considerable gift to the horticulturist was the second volume of Darwin's "Animals and Plants" The excellencies of the cultivated had arisen from the plebeian wild through the skilful selection of man Philosophy applauded the solution, but what was selected, how it arose, and how it was perpetuated, philosophy was content to ignore

Of all these things the gardener took little heed He continued his usual practice, and the flow of newer and more beautiful things went on. Then came another philosopher who was also a gardener Gregor Mendel disclosed the nature of heredity, and the disclosure gave more than a hint as to the manner in which fresh variations arose But Mendel's posthumous achievement was even greater He forced the philosopher himself to become a gardener, and to this new combination William Bateson, its first great exemplar, gave the name geneticist Then fortune felicitously intervened John Innes, of the Manor House at Merton, died, bequeathing property and money for the furtherance of horticulture The trustees, in appointing Bateson as director of the new institute, showed both foresight and courage, for there was not a little head-shaking over the matter in horticultural circles To the third philosopher was given opportunity and a garden, and this book, dedicated to his memory by two of his old pupils and colleagues, sets forth the outcome from the horticultural point of view

Following a brief introduction to Mendelian principles the volume is chiefly concerned with polyploidy and incompatibility, both phenomena of paramount importance to the horticulturist, in the elucidation of which the John Innes Institution has played a major part With the establishment of the chromosome theory of heredity by the *Drosophila* workers in America, more and more attention was paid to the chromosome content of other forms of life, and it soon became apparent that many of the more marked horticultural varieties show marked differences in the number of their chromosomes, generally in the direction of increased number as compared with the wild or more primitive forms Sometimes this increase is of the nature of simple doubling of the sets already present, as in the giant forms of the Chinese primula In other cases, different sets of chromosomes were found to be 'superadded', leading to the formation of a new type of plant, self-fertile and breeding approximately true to type but sterile with the parent forms—in short, a new species So arose *Primula kewensis* from *P floribunda* and *P. verticillata.*

The possibilities inherent in polyploidy are enormous, and the complexities also are very great. Yet if the horticulturist is to understand his material and to continue to make headway he must have some acquaintance with the chromosomes and their vagaries, and nowhere will he find

a better introduction to this study than that which is here provided It was a happy thought on the part of the authors to illustrate their teaching by an account, partly historical and partly analytical, of various flowering plants and vegetables For each plant may differ in the course of its civilised progress The sweet pea has progressed by means of simple gene mutations alone, to this the Chinese primula has added polyploidy, while into the garden dahlia has entered hybridisation also, and we would commend the section dealing with this plant as a résumé of one of the most beautiful pieces of analytical horticulture on record

Fascinating as is the study of polyploidy in the flower border, it is of more practical importance in the orchard. Cox may be the perfect apple and Comice the perfect pear, but each has its short season and other drawbacks, and the localities are limited where they can be profitably grown There is both room and need for many finer varieties than now exist But, as earlier workers have found, breeding trees is a slow business and full of disappointments Some of these in the past have been due to the existence of polyploidy among many of our best varieties, which were those naturally chosen to breed from On this subject the authors offer many illuminating facts as well as a valuable discussion which should be most helpful in guiding future work

The existence of polyploidy is not the only difficulty with which the breeder of new fruits has to reckon Many varieties show what is termed 'incompatibility' with one another The pollen of variety *A* may be perfectly good, yet unable to fertilise *B*, though with *C* it will cause the fruit to set Careful and long-continued analysis at the John Innes Institution has shown that the many varieties of cherry fall into definite groups such that the members of a given group all show incompatibility with one another, yet at the same time their pollen can fertilise members of other groups and lead to fruit production The existence of such groups—and they are found in other fruits besides cherries—is based upon definite genetical factors Such knowledge is not only essential to the plant breeder, but is also most important to the grower when he comes to select varieties in the planning of his orchards For where incompatibility is found, judicious inter-planting of different varieties is essential to good results

As sound practical horticulturists, the authors have throughout kept the gardener in the fore-front of their minds, and no gardener of imagination and intelligence can fail to be grateful for their clear and sympathetic exposition of the present state of knowledge in these matters But as is fitting and inevitable, philosophy keeps breaking through Illuminating as this book must be for the trained gardener, we venture to think that it will be even more so for those who are sometimes termed 'pure scientists'. For in their analysis of garden plants the authors are continually shedding fresh light on the nature of species itself It is clear that the manifestation of variety in the living thing is intimately bound up with the nature and arrangement of the chromosomes About these little bodies much has already been learned through hybridisation and the systematic study of polyploidy Recently, in X-rays the geneticist has found a new tool He is already learning to produce new variations, though as yet the tool is far from being under control Control, however, will come in due course, and with it perhaps the advent of the fourth philosopher

Fossil Birds

Handbuch der Palæornithologie. Von Prof Kálmán Lambrecht Pp xix+1024+4 plates (Berlin Gebruder Borntraeger, 1933) 108 gold marks

THE fossil remains of birds are usually only isolated bones Even these are rare in most of the rocks which contain them, and those which have been collected are widely scattered among numerous museums The few known bones of a Pliocene ostrich from Samos, for example, are in four museums in three different countries We therefore welcome an exhaustive treatise on these fossils by Prof K Lambrecht, of Budapest, who has devoted many years to a study of the subject He has not only prepared a critical summary of the literature, but has also examined the actual fossils in museums, and can thus write with first-hand knowledge He has made many new observations, and he has also discovered important specimens which have hitherto been overlooked His work is well illustrated with outline drawings and beautiful photographs, many of them original, and a few copied from published figures which are not readily accessible

Prof Lambrecht begins with a general account of the osteology of birds, accompanied by a series of good drawings which explain the various technical terms used in describing the bones He then prefaces his systematic account of the fossil birds by a short historical introduction, which is illustrated by portraits of Richard Owen, A. Milne-Edwards and O. C Marsh, who were pioneers in describing and interpreting the fragmentary specimens. He also briefly summarises his classification into orders, beginning with the Archæopterygiformes and ending with the Passeriformes, without any grouping into larger divisions He does not recognise the Odontornithes of Marsh,

but places the Cretaceous toothed birds close to the surviving orders to which he considers they are related

The systematic descriptions are most exhaustive, with long bibliographies and numerous tables of distribution of the genera and species of the several orders Some of the lists of the literature may perhaps be considered too exhaustive, even a story of Aepyornis Island by H G Wells, for example, is included There are, however, many interesting novelties which enliven the technical compilation, such as the first photographs of the fragment which Marsh named *Laopteryx*, and drawings of the rudimentary wing bone of *Aepyornis* There is also a useful stratigraphical and geographical list of genera and species

A final chapter on the general palæontology and palæobiology of birds is remarkably comprehensive Modes of fossilisation, feathers, footprints, eggs, gizzard stones, coprolites, guano and even nests are discussed A fossilised nest from the Upper Miocene of Wurtemberg, which is shown in a beautiful photograph, is especially noteworthy Then follow remarks on the ways in which birds are adapted to their different surroundings and modes of life, and the concluding pages are devoted to the problems of evolution

Prof Lambrecht is indeed to be congratulated on having produced a handbook which is not only indispensable for all who study birds, but is also filled with matter of interest to every biologist

A S W

The Planet Mercury

La planète Mercure et la rotation des satellites étude basée sur les résultats obtenus avec la grande lunette de l'Observatoire de Meudon Par E -M Antoniadi Pp v+76+3 plates (Paris Gauthier-Villars, 1934) 18 francs

THIS little book does not belie the author's international reputation—the old adage, "Small bulk but guid gear", sums it up tersely, containing as it does matter to please and interest both the general reader and the serious student of astronomy The monograph contains five chapters, namely generalities, transits of Mercury, geography of Mercury or hermography, and rotation of the planet, atmosphere and mists of Mercury; the physical conditions of the planet, and a table of contents

From the comprehensive opening summary of the oldest records with references, it is worthy of note that the early Egyptians, Chaldeans and Greeks recognised the identity of the evening and morning star Again, the Egyptian priests, followed by the Pythagoreans and others, and much later, by Copernicus, discovered that Mercury, like Venus, moved round the sun Orbital elements and an explanatory diagram of the varying elongations are given together with the ancient names, evolution of symbols personifying quick motion, old and modern colour and brightness comparisons, Hevelius's discovery of the phases and that of their deficiency of Schroeter

Transit records from 1631 until 1927, disc distortion at ingress and egress, light spots and the phenomenon of the complementary fringe around the black disc masking the extent of a Mercurian atmosphere are discussed

The geography of Mercury, or hermography, and the rotation of the planet form the third and principal chapter—one of absorbing interest Summarising the work of the past and present centuries, M Antoniadi, authorised by M Deslandres to make a systematic research on Mercury, describes his observations from 1924 until 1929 with the 0 83 metre (33 7-in) refractor of the Meudon Observatory His results and those of other observers agree generally with Schiaparelli's work both in the form and location of the surface features and the equality of the rotation period of 87 97 days with the revolution round the sun A chart (Schiaparelli's is also reproduced for comparison) shows the light and dark markings appropriately christened from the Greco-Egyptian mythology of the great god Mercury Generally, the observations show that (1) the light areas are more extensive than the dark regions and show luminous spots as on Mars and the moon; (2) the visible portion of the southern hemisphere is darker than the northern as with the earth and Mars

Libration, due to uniform angular rotation with variable orbital speed, illuminating 228° in longitude of the planet and leaving 132° in continual darkness, is explained Tidal frictional force maintaining similar conditions on large satellites is also investigated

Discussing the meteorology of the thin yet deep atmosphere of Mercury, with its shifting banks of suspended dust, the low albedo of 0·13 is inferred for reflection from a rough surface covered with broken rocks and dust

That tin and lead would melt under a vertical sun reveals a very hot surface A vivid—in part 'dramatic'—description of the state of Mercury makes no reference to radioactivity or to pressure of radiation M. Antoniadi quotes Flammarion regarding life—"The forces of Nature produced different effects according to circumstances, and that all life cannot be excluded from Mercury", again, in p 69, the author admits the possibility of microbic life at the Mercurian poles The reviewer agrees, and thinks that although the planets may not support *terrestrial* life, the

probability of cosmical life, of a form outwith our conception, might be envisaged

A survey of the sky as seen from Mercury concludes the memoir, which is embellished by three plates and many fine drawings and diagrams

H McEWEN

French Psychology

Nouveau traité de psychologie Par Prof Georges Dumas Tome 2 *Les fondements de la vie mentale* Pp vi+612 Tome 3 *Les associations sensitivo-motrices, l'équilibre et l'orientation, l'expression des émotions, les mimiques, le langage* Pp vi+462 (Paris Félix Alcan, 1932–1933) 100 francs each.

THE French school of psychologists, led by Dumas and Piéron, have many important investigations to their credit In their work, the refinement of detail is happily harmonised with those broad synthetic views which connote the classical character of the French mind The collective treatise on psychology which will be completed in nine volumes, and of which vols 2 and 3 are under review, is an outstanding result of team work relating to one of the most exacting of sciences. While the first volume, published some time ago, dealt mainly with questions of method, the second volume is devoted to the foundations of mental life Here we find a detailed analysis of the relations between various kinds of stimuli and the reflexes, movements and secretions of the body, also of the sensitive and affective elements of mental life, such as the various types of sensations, pleasure and pain, emotions and tendencies, and finally of imagery and the relations between image and thought All these questions are well treated by G Dumas, H Piéron, A Mayer, B Bourdon, J Larguier des Bancels and I Meyerson The study of the affective states (especially of emotion and of pleasure and pain) by Prof G. Dumas and the monograph on images by I Meyerson are remarkable examples of orderly exposition and unbiased discussion of results

The third volume deals specifically with the major sensory-motor functions, such as orientation and bodily equilibrium, the expression of emotions, mimicry and language Prof Dumas rightly holds that no psychological functions are purely sensory or purely motor, though, of course, when analysing them one of these aspects may be stressed to the exclusion of the other The study of vision, for example, which is generally considered as a purely sensory function, involves an important background of motor responses and muscular reflexes. The chapters on the expression of emotions are most interesting in their details, both in regard to the methods adopted and to the cases observed or quoted Attention, surprise, astonishment, joy, sadness, fear and anger are analysed not only as mere expressions of emotions, but also as results of physiological stimuli Indeed what adds to the value of this volume is the fact that all experiments and observations are explained or discussed with due consideration of the physiological changes involved in each case The two monographs by A Ombredane on orientation and on language show the same qualities

The value of the first three volumes of the "Nouveau Traité de Psychologie" causes one to await with eagerness the publication of the rest of this great work It cannot be said that the French psychologists form a distinct and original school of thought But their work is important precisely because of their detachment from any labelled group of scientific workers Prof Piéron might perhaps be counted as a behaviourist, since he was led by his animal studies to define psychology as the study of behaviour before Watson used that formula But Prof Piéron is more clear-headed than the American behaviourists, as Prof Wordworth pertinently pointed out, for he sees no necessity for calling into question the individual's testimony to his own consciousness Prof Dumas, too, gives much weight to introspection In spite of its difficulties, this method is really indispensable in psychology, since it has furnished the suggestion even for the objective studies that have been carried on, and since it supplies the personal interest which one finds in psychological results

The main characteristics of French psychology, however, are its emphasis on the biological basis and the social setting of the individual's activities, and also its interest in psychopathology These characteristics are very prominent in the volumes under review and enable their authors to steer a middle course among the growing complexities of psychological research T GREENWOOD.

Teaching of Elementary Physics

A Textbook of Physics By E Grimsehl Edited by Prof. R Tomaschek Vol 2. *Heat and Sound* Pp xi+312 12s 6d net. Vol. 3 *Electricity and Magnetism* Pp xiv+685. 25s. net. Vol 4. *Optics.* Pp xii+301+17 plates 15s net. (London, Glasgow and Bombay: Blackie and Son, Ltd, 1933)

THE teaching of elementary physics in British schools and universities will be materially assisted by the appearance of these three volumes of Dr Grimsehl's "Textbook". The high standard set in the first volume has been maintained throughout in the present volumes, and in certain respects the English edition may be said to be an improvement on the German original

The translators have, on the whole, done their work well and have added useful explanatory notes whenever the original has appeared to be lacking in detail In vol 2, for example, Robert Mayer's calculation of the numerical relationship between work and heat from the difference of the specific heat of gases at constant pressure and constant volume is rightly criticised in a footnote which quotes from the works of Tait and Roberts

Among the special subjects treated in this volume are atomic and molecular rays (Dunoyer), zero-point energy, and Nernst's heat theorem In some cases the references are too brief to be considered useful, as on p 277, where Behm's sonic depth-finder is mentioned without a suggestion as to how it works The same applies to the electrical excitation of quartz crystals for producing ultra-sonic vibrations (p 265), a subject on which much interesting information might have been compressed into a small space The section on heat engines is clearly written and well illustrated Not the least interesting feature is the great number of biographical notes scattered throughout these volumes. We read on p 152 that K F Braun, who followed up and firmly established Le Châtelier's principle, was a professor at Strasbourg in the years preceding and during the Franco-Prussian War, and that in recognition of his valuable work in wireless telegraphy he shared the Nobel prize in physics with Marconi in 1909 He died in the United States, where he was staying at the outbreak of the European War and had been interned

The section on waves is comprehensive, resonance and coupled oscillations are treated with great didactic skill The last part deals with sound Here the treatment of Kundt's tube experiment must be regarded as inadequate But the blemishes are few, and the volume deserves a warm welcome

Vol 3 has been considerably revised and supplemented by Prof. Tomaschek as compared with the last edition issued by the original author The result is in every way excellent Many novel methods of treating electrical phenomena are given and it is gratifying to find that difficulties have not been shirked For example, a simple but thoroughly useful account of the electron theory of metals is given and is afterwards applied to explaining the ultimate mechanism of electromagnetic induction In a small section on "Waterfall and Thunderstorm Electrification" there is a quotation from Lenard that "no double layer is formed at the interface between water and air" The succeeding sentence runs . "on the contrary small droplets of diameter less than 10^{-4} cm prove to be negatively charged when detached from the water surface" An examination of the context shows that "on the contrary" is misleading here as a translation of the German word *hingegen*, which has only the strength of "however" on this occasion For we know from Lenard's own work, as is mentioned on the next page, that an electrical double layer *is* actually formed at the surface of water but within itself Attention may be directed to a slip in the index where a joule is given as equal to 10^7 dynes, it is given correctly, however, in the text

As these books by Dr Grimsehl make a point of furnishing biographical and historical details connected with important physical discoveries, it is surprising to find no mention of the earliest determinations of the elementary electric charge Reference is made only to the work of Ehrenhaft and Millikan This is a case where an illuminating note by the translator would have been welcomed In some instances the account is rather meagre, for example, the treatment of potentiometers (p 233) and of the ballistic galvanometer (p 317), and occasionally we find that familiar English expressions have been omitted English, and for the most part also foreign, students are accustomed to seeing the left- and right-hand rules linked with Fleming's name, and the theorem concerning the equivalent magnetic shell associated with Ampère Nor is Townsend's name mentioned in connexion with ionisation by collision, a discovery of outstanding importance

The chapter on high-frequency oscillation is very clear, but there is no mention of electrodeless discharges Again, in dealing with thermionic valves, it would have been an advantage to introduce accepted English terms such as differential internal resistance, anode slope resistance and so forth On p 598 the Schottky-Langmuir formula deserves equal emphasis with that of Barkhausen

Many readers will have been unacquainted with the Johnson-Rahbeck effect (p 210) discovered in 1920, which makes it possible to use the force of attraction of a charged plate condenser in place of an electromagnet for mechanical action. The treatment of generators and motors is excellent and the accompanying diagrams exceptionally good

This volume is perhaps the most stimulating of the four that have so far appeared We may guess that the author is here dealing with his favourite subject The way in which the material is presented confirms that Dr Grimsehl's high reputation as a teacher was fully deserved Vols 2 and 3 have been translated by Dr L A Woodward.

Little more need be said of vol. 4 than that it maintains the high standard of the preceding volumes of the series and that the illustrations are quite exceptionally good in many cases, as for example, plate VII facing p 92, which shows the tracks of rays through thick lenses, and plate XII, which indicates how a cardioid condenser

(of the Siedentopf type) acts Although a good plate (XIII, facing page 154) is given of spectra photographed by Gerlach and Schwertzer for deducing the composition of a mixture of tin and a small percentage of cadmium, no reference is made in the text to the diagram or to the fundamental principle underlying photographic spectrophotometry There is a good section on autochrome photography but no account of ordinary photographic processes, or of the density curves of photographic plates There is an interesting laboratory experiment devised by Dr. Grimsehl himself to explain the formation of rainbows Some of the less well-known effects of light are conveniently enumerated, such as the Weigert effect (action of polarised light on exposed photographic paper)

This volume, which has been translated by Winifred M Deans, will be useful both as a textbook and as a reference book for those acquainted with only the elements of the subject No doubt the last volume of the series (on atomic physics) will supplement the section dealing with spectral lines, so that the five volumes will constitute a complete elementary course in physics

H L B

Short Notices

Dipole Moments a General Discussion (Reprinted from the *Transactions of the Faraday Society*) Pp ix + 677 904 + lxxxvi (London and Edinburgh Gurney and Jackson, 1934) 21s net

THIS reprint contains the account of the proceedings of the General Discussion held in April (see NATURE, **134**, 802, May 26, 1934) together with an appendix consisting of a table of values of dipole moments for which Dr N V Sidgwick and two collaborators are responsible This appendix is a most valuable part of the report, since it contains not only the numerical values of the moments of a large number of substances, but also references to the original publications and such information as may be required in the interpretation of the data The discussion dealt with the dielectric constant, the determination of dipole moments and the interpretation of dipole moments, and the papers contributed and the discussions on them are now available The volume is one of considerable interest and value, and the Faraday Society is to be congratulated both on the success of the meeting at Oxford and also on the very material addition to knowledge which is represented by this volume The type of binding of the reports has been improved

The Surgery of the Sympathetic Nervous System By Prof George E Gask and J Paterson Ross Pp xii + 163 + 13 plates (London Baillière, Tindall and Cox, 1934) 16s

THE surgery of the sympathetic nervous system is yet in its infancy Our knowledge of this system itself is none too well developed, so that its surgery must of necessity remain in the experimental stage until our knowledge of the pathology is sounder

The authors give us the results of their work in the surgical unit at St. Bartholomew's Hospital The main body of the work is divided up into three divisions dealing with sympathectomy for disorders of (*a*) the circulation, (*b*) the visceral motor mechanism and for the relief of pain Their results in some types of case which have been regarded as more or less intractable to treatment are surprisingly good, and we hope that the work, when fully developed, will yield results of even startling character.

Bilder zur qualitativen Mikroanalyse anorganischer Stoffe Zusammengestellt von Prof W Geilmann Pp 12 + 40 plates (Leipzig Leopold Voss 1934) 8 gold marks

THIS collection of 240 photomicrographs in 40 plates illustrates the forms of the particles of precipitates produced by analytical reagents The reproductions are exceptionally good, and the forms of the crystals, the degrees of magnification and the conditions of precipitation are given, so that the results are free from ambiguity The photomicrographic procedure is also briefly described

Although the utility of microanalytical methods in a large field has undoubtedly been over-estimated by enthusiasts, they can play a very useful rôle in the confirmation of ordinary qualitative analysis in normal cases, and in cases where only a small quantity of material is available they become of increasing importance Prof Geilmann's book is very handy in size and contains practically all the cases met with in normal practice, so that it may be recommended as likely to find favour in analytical laboratories It is convenient in size, as compared with some earlier publications in atlas format, and will meet the requirements of all except the specialist in this field.

Materiewellen und Quantenmechanik: eine Einführung auf Grund der Theorien von de Broglie, Schrödinger, Heisenberg und Dirac Von Prof Dr Arthur Haas Vierte und Funfte, verbesserte und abermals wesentlich vermehrte Auflage Pp viii + 299 (Leipzig , Akademische Verlagsgesellschaft m b H , 1934) 7 80 gold marks

THE first German edition of this work and its English translation were reviewed in NATURE of March 9, 1929 (p 362) Since that time it has been more than doubled in thickness by the addition of chapters on parahydrogen, Dirac's theory of the electron, the positron and applications of the Fermi statistics to metallic electrons. As before, stress is laid upon fundamental principles rather than detailed mathematical proofs, for which the reader is referred to the original sources, so that the book will appeal to anyone who desires an up-to-date and, within limits, a readable account of recent work in atomic physics.

Problems and Progress in Photography*

By OLAF BLOCH, Research Laboratory, Ilford, Ltd

PHOTOGRAPHY is the recording angel of the arts and sciences, but it is to be hoped that angels of other classifications do not have to endure the insistent requests for materials possessing incompatible properties which are demanded of the photographic chemist. Perhaps the most difficult problems are presented by the physicists and astronomers, who require grainless emulsions of extremely high speed, sensitive to all the visible spectrum, or any portion of it—with extensions into the ultra-violet and infra-red regions!

For work in the neighbourhood of the Hα line, two types of emulsion are now available, one which attempts to give the astronomers a maximum sensitivity at λ6500, and another, which has fairly even sensitivity round this region of the spectrum, extends well beyond. The spectrum of meteors has been successfully photographed by Williams, of the Steward Observatory, and for this purpose an emulsion of great speed and high green sensitivity was necessary. Other recent emulsions include one with a maximum at λ5300 for work on the solar corona, and another, for lunar disc photography, of fine grain and high contrast, where an attempt has been made to compensate for the low speed by extreme colour sensitising.

In the region of atomic physics, properties of another kind are desirable. For α-particle and proton track work, it is essential that the grain of the emulsion should be fine, resolving power high, and that the unexposed portions should yield but few or no silver grains upon development. Normally, emulsions have about 3.5×10^6 such grains per cm.^{2} when developed without exposure, the average size of these being dependent upon the size of the silver halide crystals; but a recent product of the emulsion maker's art gives almost complete freedom from these.

Quite different requirements are necessary for work with atomic rays and in the extreme ultra-violet. Here the radiation has little penetrating power and is readily absorbed by gelatine. Hence, only sufficient gelatine must be used to bind the silver halide, or the crystals of the latter must be made to project beyond the gelatine surface—a rock-garden effect! The Schumann plates, always somewhat untrustworthy, are of the former type, and recently an emulsion of the latter kind has been produced which appears to be sturdier and more constant in its properties.

There are two main sections in photography: first, its applications, including the important function of recording; and secondly, the internal problems of the subject, dealing largely with the mechanism of emulsion making and the effect of light upon the sensitised silver halide. The function of gelatine in emulsion making is complex: first, it holds silver halide in suspension, a suspension by no means perfect, since sedimentation usually takes place when the liquid emulsion is allowed to stand. Secondly, it is the principal means by which speed can be obtained; and thirdly, it prevents too rapid reduction of the unexposed silver halide in the developer, whilst permitting a sufficiently slow reduction of the latent image to enable control to be exercised. The amount of gelatine necessary to produce suspension is very small, so little as 1 gm. of gelatine per 100 gm. of silver halide being effective. Discussion is still rife as to the mechanism of the silver halide gelatine system, one argument being that bodies in the gelatine, having the iminazole and azine linkages, tend to form adsorbed layers of the protective colloid on the silver halide surfaces. It has not been found possible to remove the gelatine entirely from the latter by centrifuging and subsequent washing, and whether the retention of the gelatine is mechanical or otherwise, it would probably not be without effect upon the resulting emulsion.

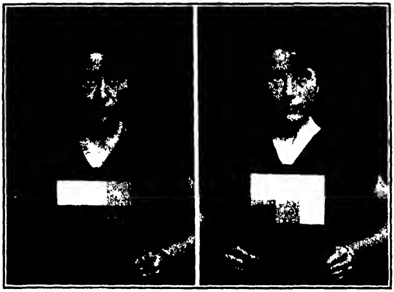
The silver halides are all light-sensitive and darken when exposed to light, free halogen and metallic silver being amongst the reaction products when the intensity is sufficiently high, but exceedingly low intensities suffice to produce a developable latent image when the emulsion is in a highly sensitive condition. Very little is known about the changes which occur in these circumstances. It is at present generally held that the first action of light is the splitting off of electrons from the bromine ions in the silver bromide, with the consequent discharge of silver ions forming atoms of free halogen and free silver, the emulsion possibly becoming developable by reason of the altered position of the electric charges. The photo-electric effect does not appear to play a part, but it has been found that the photo-conductance of silver bromide in exceedingly thin layers increases and decreases in a manner corresponding to its spectral sensitivity in energy terms, the photo-sensitive units probably being the bromide ions. Also, in the case of a photo-voltaic cell consisting of electrodes of silver bromide coated on silver and in a bromide solution, the illumination of one pole sets up potential differences. In most of this

* Substance of three lectures delivered at the Royal Institution on October 30, November 6 and 13, 1934.

work the suggestions are purely theoretical, or have resulted from experiments on precipitated or deposited silver bromide *per se*, or of silver bromide crystals in an isolated condition. Little of the work deals with the silver halide in its actual emulsion form. Such evidence as can be obtained depends almost entirely upon the action of a reducer in order to study the effect of light in producing the latent image, and we have very little real knowledge of the state of affairs existing in the silver halide crystal in emulsion form either before or after exposure. The conclusions reached at present are largely inferential and this remains one of the unsolved problems of photography. Also, we have no exact knowledge as to the relationship between light quanta and latent image.

acts by deforming the ultimate structure of the silver bromide, thus affecting the silver and bromine ions, so that the photo-chemical decomposition might be more localised with a more ready splitting off of the bromine electrons. There is no doubt of the main facts, but it seems probable that it is only a particular case, since other substances not containing sulphur can act similarly, though less effectively, in the case of the desensitised gelatines.

A great deal has been done in the investigation of the phenomenon of development, and, in general, two views may be said to hold the field: one is that the reduced silver is dissolved in the developer and re-deposited; the other formulates the idea that the reducing



(a) (b)

FIG. 1. (a) Negative made on the unexposed portion of the characteristic curve of an emulsion and developed for a long time to secure maximum contrast. (b) Negative made on the straight line portion of the characteristic curve of the same emulsion and developed for a short time to secure minimum contrast.

One of the interesting discoveries was the existence of minute quantities of sulphur compounds of the thiocarbamide type in gelatine. When the gelatine was sufficiently purified to remove these, emulsions prepared with it were of low sensitivity, and the restoration of the sulphur-containing compound, at almost any stage of the emulsion making process, restored the sensitivity. In practice, the original sensitivity cannot be greatly exceeded by increasing additions of the sulphur compound beyond a certain point, since fog results. There would appear to be an adsorption of the sulphur compound on to the silver halide, subsequent reaction yielding silver sulphide in the form of specks which are supposed to be the sensitive nuclei.

Much work has been done upon this subject, and it has been supposed that the silver sulphide

ions of the developer are first adsorbed on to the silver, a re-arrangement afterwards occurring which gives metallic silver and oxidised reducer. The function of gelatine as a protective agent in reduction is not complete, since all emulsions show some reduction if the reducer is allowed to act for a sufficiently long period.

The mode of expression of the speed of an emulsion is still a vexed question, since it is impossible that one figure can express a variety of different properties in any one substance. Speed may depend upon the portion of the emulsion curve which is employed for the particular purpose in hand (Fig. 1, *a* and *b*), and a knowledge of speed alone need by no means be the first consideration—gradation, resolving power, graininess and other properties may be of equal or greater importance.

The older Hurter and Driffield method of expressing the speed depends upon the straight line portion of the characteristic curve, and this is a measure of the contrast (gamma) of the emulsion as well as of its speed, and is often inadequate More modern methods, including the German DIN (*das ist normal*) system, depend upon some function of the under-exposure curve and yield a speed number which is, perhaps, more in accord with the requirements of those who take instantaneous camera pictures There are many obstacles in the way of giving a brief statement as to the properties of any one photographic emulsion, the variation in the gradation and length of both the under-exposure and the straight line portion of the curve, the shape of the over-exposure curve and the exposure point at which it begins to function, the failure of the emulsion to obey the reciprocity

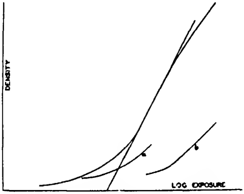


FIG 2 Characteristic curve of the emulsion used in Fig 1 Portion used in Fig 1*a* is marked *a*, that used in Fig 1*b* is marked *b*.

law, may all enter into one or other of the uses to which the sensitive material is to be put. It is certainly important that some indication of the photographic quality of the material used should be given, but it is not possible to accomplish this satisfactorily until a much larger proportion of the camera-using public is educated to a higher photographic standard.

Two important properties of emulsions are resolving power and graininess. The former is a very complex quality, depending upon a large number of factors It has been defined as the capacity of an emulsion to resolve a number of lines and spaces per millimetre, the lines and spaces being of equal dimensions. Some of the factors influencing it are the maximum contrast obtainable and the shape of the characteristic curve, the amount of scatter due to the film, its graininess, its spectral sensitivity, the size of the image, etc. Other factors are shape, range of contrast and spectral quality of the object, the amount of exposure, the treatment in processing, the aperture of the lens and the spectral quality of the light used for taking the photograph. Some of these operate in antagonistic directions for example, resolving power decreases with grain size, but since emulsions of very small grain size are somewhat slow, their use is impracticable where high speed is required In the same way, small lens apertures are not possible in the same circumstances

It is necessary, for many purposes, to enlarge the photographic image, for this reason, the cinematograph and the increasing use of the small precision camera have made the question of graininess an important one. Graininess might be defined as the distance at which the image of the silver deposit no longer appears uniform at constant magnification, or the magnification at which the silver deposit no longer appears uniform viewed from a constant distance The question is a physiological one and a standard is therefore difficult to set up Various methods, mostly visual, and chiefly comparative in character, are used for determining this property Graininess depends mainly upon the emulsion itself, factors being the size of the original silver halide crystals and the extent to which clumping occurs, either in the emulsion itself, or as a result of development Modern emulsion making has shown considerable advances in the direction of producing faster emulsions possessing a relatively fine grain, and it seems probable that these methods can be still further developed

Optical sensitising is the term applied to the alteration of the spectral sensitivity of an emulsion by the addition of a dyestuff which is adsorbed by the silver halide and confers upon it an added sensitivity in the neighbourhood of the absorption of the dyestuff So far as experimental data are at present available, the dye can be removed by the use of an inert solvent suitable for the particular dyestuff, with consequent loss of the added sensitivity The sensitising power varies with the chemical composition of the dye, and the addition of substituent groupings can have a large effect, or the substitution of one grouping for another (for example, the change from a dimethyl to a diethyl grouping) can cause marked deterioration or improvement.

Ordinary emulsions are sensitive from about λ2100 to about λ5200, and optical sensitising does not greatly affect this inherent sensitivity The amount of dye needed for optimal sensitising can be extremely small, in the case of one dye, for example, it is of the order of 1 gm. molecule of the dyestuff to 357,000 gm. molecules of silver bromide. In another case, at the other end of the scale, it is as large as 1 gm molecule of the dyestuff to 6000 gm. molecules of silver bromide.

The smaller grains of the emulsion adsorb more dye than the larger, possibly owing to their greater area per unit mass, and this accounts for the higher contrast obtained when exposure is made to light of a longer wave-length than that to which the emulsion was originally sensitive, since the smaller grains give steeper gradation than the larger and become more highly sensitive in consequence of the increased dye absorption.

Bancroft, Sheppard and many others have put forward a number of theories to account for the phenomenon of colour sensitising, and we have still almost everything to learn about its mechanism, but a good deal of recent work is likely to go far to clear up the chemistry of the dyestuffs employed. We can classify these into a number of chemical groups, and can generally say which particular compounds are likely to sensitise and which are not, from a consideration of their constitution; we can forecast with fair accuracy the region over which they are going to sensitise the emulsion, and in some cases foretell whether they will be weak or powerful sensitisers. In the older days, erythrosine was almost the only dye used, and sensitised the emulsion up to about λ5800, but with the advent of the cyanine group of dyestuffs, great progress has been made and it is now possible to sensitise an emulsion, at will, to almost any part of the visible spectrum. This class may be thus represented:

CYANINES

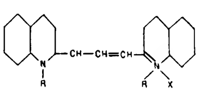
CARBOCYANINES

DICARBOCYANINES

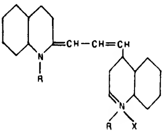
TRICARBOCYANINES

A and *B* represent several types of nuclei and the compound may be unsymmetrical when *A* and *B* are different nuclei. The number of CH groups is odd. *R* may be methyl, ethyl, allyl, etc., and *X* may be chloride, bromide, iodide, *p*-toluene sulphonate, etc. Substitution may also take place in the chain, where one of the CH groups may be replaced by an alkyl, aryl, ethylene or phenylene group, or there may even be a halogen substituent in the chain. Generally speaking, as one increases the chain length, the dye becomes more unstable and the photographic products prepared with it more unstable. As the length of the chain is increased, the dye absorption and sensitising power travel towards the red end of the spectrum, each additional pair of CH groups moving the absorption by about 1100 A. towards the red end of the spectrum.

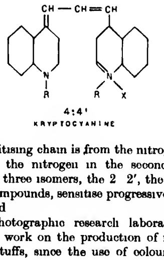
The case of the three carbocyanines with the following formulæ is of interest:



2 2′
PINACYANOL



2′4′
DICYANINE



4:4′
KRYPTOCYANINE

The sensitising chain is from the nitrogen in one nucleus to the nitrogen in the second nucleus. Hence, the three isomers, the 2 2′, the 2 4′ and the 4 : 4′ compounds, sensitise progressively farther into the red.

Many photographic research laboratories are actively at work on the production of new sensitising dyestuffs, since the use of colour sensitive emulsions is varied and important. Competition in the photographic industry is very keen and considerable progress has been made in recent years, but in many branches empiricism is still much in advance of proven theory.

Electrical Developments in the Soviet Union

THE growth in the use of electrical energy in the Soviet Union in connexion with the Government's industrial development schemes were outlined in a paper read to the Institution of Electrical Engineers by Mr Allan Monkhouse on January 10 He gave interesting details also of the development in the use of peat fuel in large power stations. The first State-planning organisation set up by the Government was the State commission for the electrification of Russia appointed in 1921 In forming this commission, Lenin emphasised the necessity of providing an abundant supply of cheap electrical power as a basis on which industry could develop From 1923 onwards the construction of fifty-six large power stations and the erection of 8,000 miles of high-tension overhead wires with all their distributing substations has been a most spectacular development The rapid growth in the use of electrical power during the last ten years is shown by the increase in the monthly winter output, from 750 million units to 11,000 million units

The industrial districts of the north, which comprise Leningrad, Moscow, the cotton manufacturing district centred at Ivanovo Vosnesensk and the Gorki (Nijni Novgorod) district, where many large engineering works are being constructed, are far removed from the bituminous and anthracite coal-fields of the Ukraine or the oilfields situated on the shores of the Caspian Sea For economic and strategic reasons, it was considered necessary to make the northern industrial areas independent of these fuel supplies. Special attention was therefore concentrated on the development of stations burning peat and brown coal.

A survey of the peat areas of the U.S.S.R. indicates that approximately 42 per cent of the world's peat resources are located in that country. It is calculated that 30,460 million tons of fuel are available south of lat. 60° N North of this line, the vast peat resources of the tundra have as yet only been partially surveyed. Using a special form of shaft-chain grate, it was found that the efficiency obtained was quite satisfactory The Balakna power station in the Nijni Novgorod district is the largest peat-burning power station in the world. Its present capacity of 158,000 kw. is being increased to 204,000 kw. Of the eighty-one official stations, approximately 30 per cent operate on peat fuel. A special process of peat-winning known as the hydro-peat process has been developed. The peat is dislodged from the bog with a high-pressure sluicing apparatus, and the mixture of peat and water is then pumped into specially prepared drying fields. After a few days' drying, a special form of tractor with cutter wheels is driven over the field and leaves the peat in such a form that it can be raked up easily and finally air-dried The shortcomings found initially in using peat in a power station have been in large measure overcome, mainly by experimental research

In the Ukraine and the mining districts of the Don basin, much work has been done in utilising the anthracite-waste spoil-banks, which have accumulated over a period of many years, but the efficiencies obtained have been rather disappointing

Large areas of the cities of Moscow and Leningrad are already heated with hot water circulated from the central power stations On the outskirts of these cities, large new so-called thermal-electric stations are being built for heating the new residential districts In Moscow the hot water leaves the water-heating plant in the central power station at a temperature, varying according to conditions, of between 85° and 120° C, and after making a circuit of some two miles, it returns at a temperature of 30°–35° C The pipes are laid in special conduits in the street and are covered with thermal insulation Many of the large new industrial towns are being built with the idea of all their buildings being heated from central thermal-electric power stations.

With the exception of the Ural Mountains and the Caucasus, both of which are far removed from the central industrial areas, there is not enough mountainous country to make high-head hydro-electric power stations possible But the Soviet Government has decided to build a series of large low-head hydro-electric stations on the great rivers of European Russia The dam built on the Dnieper and those being built on the Volga and the Svir have a twofold object in view, namely, providing cheap electric power and making the rivers navigable for large vessels Of the low-head stations, that on the Dnieper is the most important The pressure of transmission is 161 kilovolts, and the station supplies the works of the Dnieper Combine and the central Ukrainian network

A most important undertaking in Central Asia is the Chirchick fertiliser works, designed to produce large quantities of nitrate fertiliser for the cotton fields of Central Asia. The first station has been begun and the turbines will work with a head of 66 metres. The scheme provides for irrigating 1,250,000 acres of cotton growing land. It is interesting to notice that the Soviet authorities have called in Italian consulting engineers to lay out the hydro-electric part of this great scheme.

Some progress has been made in standardising

methods The line linking the new Svir hydro-electric station with Leningrad uses the very high voltage of 220 kilovolts The Soviet intends to electrify about 2,300 miles of railway before 1937 The pressure of 1,500 volt direct current is generally used for suburban electrification, but the voltage for the long distance main lines has not yet been fixed

Mr Monkhouse laid stress on the extreme importance the Soviet authorities attach to research and experimental work Academic and fundamental research work is receiving the closest attention, and very large electrical research laboratories have been developed All the various works and factories connected with the Electrotechnical Trust send their more complicated problems to the Central Institute in Moscow The laboratories employ 1,700 workers, about 800 of whom are men with university training The departmental chiefs are, almost without exception, men who occupy professorial chairs in the universities There is little doubt that, in electrical development, more has been achieved than in many other branches of the country's economic life

News and Views

"Letters to the Editor"

ON two occasions last year, issues of NATURE were published in which "Letters to the Editor" occupied considerably more than the usual proportion of the journal This week we are printing a Supplement of sixteen pages, fifteen of which are occupied by correspondence—and there are still many letters in type awaiting publication The number of letters we receive for this part of the journal reflects fairly accurately, we believe, contemporary progress of research in all departments of science Last year we printed no less than 597 columns of correspondence, the great majority of which announced new lines of work or made significant contributions to older established knowledge The addresses at the ends of the letters in this week's Supplement alone indicate the world-wide distribution of our correspondents The spate of letters brings its own difficulties, and we are frequently obliged to ask correspondents to reduce the length of communications, but nevertheless we are gratified to find our columns so much in demand. It reaffirms the old saying that science over rides all national barriers Recently, a short section has been introduced at the end of "Letters to the Editor", in which brief mention is made of points brought out in some of the longer letters in the preceding pages. Correspondents will realise the difficulties involved in obtaining suitable notes, and they are invited to submit paragraphs about fifty words in length which they regard as summarising the main conclusions of their communications, for possible use in this section of the journal when their letters appear

Royal Astronomical Society's Medal Awards

THE Gold Medal of the Royal Astronomical Society has been awarded to Prof E A Milne, Rouse Ball professor of mathematics, University of Oxford, for his work on radiative equilibrium and theory of stellar atmospheres A Jackson Gwilt (bronze) Medal has been awarded to Mr Walter Frederick Gale, of Waverley, N S W , for his discoveries of comets and his work for astronomy in New South Wales Prof Milne has occupied his present chair since 1929, having then moved to Oxford from Manchester, where he had been professor of applied mathematics Before going to Manchester, however, he was university lecturer in astrophysics at Cambridge and assistant director of the Solar Physics Observatory His contributions to mathematical physics and astrophysics are of particular value on account of the close contacts they represent between observational work and theoretical conceptions His essay as Smith's prizeman at Cambridge in 1922 embodied a treatment of radiative equilibrium which has proved the starting point for the greater part of the more recent work on stellar atmospheres In his Bakerian lecture of the Royal Society in 1929, on the opacity of stellar atmospheres, Prof Milne further developed a method of determining stellar temperatures and pressures, depending largely on the study of the contours of spectrum lines, that is, on the determination of their intensities at different distances from the centre of the lines Of a different character is the model of the universe conceived by Prof Milne and developed in a lecture entitled "World-Gravitation by Kinematic Methods" delivered before the London Mathematical Society in May last The striking simplicity of the method used in the construction of this statistical model, and the far-reaching character of its interpretations, open up a new vista of possibilities for cosmic research

MR GALE, the Jackson Gwilt medallist of the Royal Astronomical Society, belongs to the enthusiastic band of non-professional, or amateur, astronomers who have contributed so much to observational astronomy He is the discoverer of three comets—in 1894, 1912 and 1927—and has given close attention to the planet Mars, especially during the southern oppositions of 1892, 1894 and 1907. As first secretary, and afterwards president, of the New South Wales branch of the British Astronomical Association, Mr Gale has done much to encourage the practical study of the heavens in New South Wales, as well as to promote interest in astronomy among the general public

Geological Society's Awards

THE Geological Society of London has this year made the following awards: Wollaston Medal to

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

α–β Intramolecular Transformation of Myosin

SHORTLY after the discovery and investigation by the methods of X ray analysis[1] of the long range elastic, intramolecular transformation which takes place when the fibre substance (keratin) of hair is stretched, the possibility emerged that the elastic mechanism of muscle is similar at least in principle to that of hair[2] There is a remarkable likeness between the X ray photograph of washed and dried muscle and that of unstretched hair (α keratin), and there are, moreover, certain striking analogies between their respective elastic properties Recently, the X ray and elastic comparison between muscle and hair has been set out in detail[3], and once more the suggestion was made that the normal molecular configuration of the muscle protein myosin—first shown by Boehm and Weber[4] to give, when oriented, an X-ray photograph resembling* that of muscle itself—is that of a folded polypeptide chain system like that of α keratin, which it should be possible, by extension under appropriate conditions, to transform into a fully-extended system like that of β-keratin (stretched hair). The present writers tried to bring about this transformation two years ago by experiments on the sartorius muscle of the frog, but without success[3]

We have succeeded now in demonstrating the predicted intramolecular transformation by working with the isolated muscle protein instead of with the actual muscle We have found air-dried myosin films to have the following properties: (1) as in gelatin films, the molecular chains lie roughly parallel to the surface; (2) on moistening with water and stretching, these chains are first pulled into approximate parallelism with the direction of stretching and give rise to an X-ray photograph resembling that of muscle or α keratin, (3) on further stretching, a new photograph appears which closely resembles that of β-keratin, (4) on exposing the stretched film for a few seconds to steam, the β photograph is 'set' and intensified at the expense of the α-, exactly as in the case of stretched hair, (5) myosin films can generally be stretched in cold water to about three times their original length and, like keratin fibres, show well marked long-range reversible elasticity, the β-photograph disappearing again on contraction provided the film has not been kept stretched in the dry state, (6) when myosin films are made by squeezing the re-moistened protein between glass plates, the β-photograph is again observed, but this time with the 'side-chain spacing' normal and the 'backbone spacing' parallel to the flat surface, just as when keratin is squeezed laterally in the presence of steam[5], (7) *unstretched* myosin film, when exposed for a few minutes to steam, contracts spontaneously by about 20 per cent (artificial muscle!), exactly as does keratin that has been brought into the labile state by the action of X rays on the α-form or by the limited action of steam on the β-form[6].

* Boehm and Weber claim that the two photographs are indistinguishable, but this is at least doubtful until much more perfect photographs are available It may be said with equal justification that the photograph of hair is also almost the same as that of myosin.

In brief, myosin films are amazingly similar to the labile, or super-contracting, form of keratin which is produced by the breakdown or modification of certain cross-linkages, and in this comparison the normal contraction of muscle corresponds to the super-contraction of hair[3]. Only very imperfect chemical analyses of myosin and muscle are available—and here the physicist is in very urgent need of help—but, *if we except cystine,* the general distribution of amino-acid types appears to be similar to what has been found for keratin Does this mean that the method of formation of hair is fundamentally similar to that of muscle, except that the elastic system of hair is more or less stabilised and de-sensitised by the incorporation of relatively large amounts of cystine? In other words, are we to conclude that the hair protein is roughly speaking no other than 'vulcanised' muscle protein?

The investigation is being continued in order to try to find out the exact relations between the X ray photographs and elastic properties of muscle, myosin, and keratin We wish to express our indebtedness to the Rockefeller Foundation for financing the research, to the superintendent of the Cambridge Low Temperature Research Station for his kind co-operation, and to Dr E C Smith of that laboratory for the invaluable supplies of fresh myosin which have so far formed our exclusive experimental material[7]

Natural and Artificial Radioactivity of Potassium

THE question of the origin of the radioactivity of potassium has been much discussed in recent years[1]. The possibility, however, of producing new radioactive isotopes artificially has opened up a new line of attack on this problem. Quite recently Amaldi, D'Agostino, Fermi, Pontecorvo, Rasetti and Segrè[2] have found that, by bombardment of potassium with neutrons, a new radioactive isotope of potassium is produced having a period of 16 hours. Potassium having two stable isotopes, 39 and 41, it is not possible to draw conclusions from these experiments on the mass of the new isotope. The problem can be settled, however, from the fact that the new isotope of potassium can also be produced by bombarding scandium with neutrons. By experiments in this laboratory in which I have been kindly assisted by Hr. Høffer Jensen, we find that scandium can be converted into a radioactive isotope of potassium. As scandium has only one isotope (45) this conversion must take place according to the equation

$$_{21}Sc^{45} + _0n^1 \longrightarrow _{19}K^{42} + _2\alpha^4.$$

As the potassium obtained by us has the same period as that found by the Italian workers, we have to conclude that in their experiments it was K^{41} which captured a neutron and was converted into K^{42}. In our experiments we bombarded scandium oxide with neutrons produced by a mixture of beryllium and radium emanation, thus applying Fermi's beautiful method. The scandium oxide was dissolved in hydrochloric acid and, after the addition of 0.15 gm. of sodium chloride and the same amount of calcium chloride, precipitated with ammonia. The calcium present in the filtrate was removed as oxalate and found to be inactive. The remaining sodium chloride, however, was found to be active and to contain the potassium isotopes looked for. This decayed with a period of about 16 hours, emitting very hard β rays of approximately 1.2 million e.v.

From my comparison of the radioactivity and the atomic weight of potassium fractions obtained by distillation processes (partial separation of isotopes), it follows that the mass of the isotope to which the natural radioactivity of potassium is due can only be 40, 41 or 42. The first mentioned figure is obtained if we accept Baxter's analysis of the fractions, while that of Hönigschmid is only compatible with 41 and 42. Knowing now that the isotope 42 has a short life (16 hours) we are restricted to the alternative 40 or 41.

From measurements with the mass-spectrograph, we know that K^{41} is present in potassium in the extent of 7 per cent. From this figure and the number of β-particles emitted per second by 1 gm. of potassium, it follows that, if the natural radioactivity of potassium is due to K^{41}, it has a period of 10^{13} years. The hypothetical isotope K^{40} should have a much shorter life as this isotope has not been revealed by measurements by the mass spectrograph. From this fact the upper limit of its period can be stated to be 5×10^{10} years. A lower limit, 10^{8} years, is given by the calcium content, potassium content and geological age of old minerals. Presumably when potassium is bombarded by neutrons, K^{39} captures neutrons as well, but since the resulting K^{40} has a long life, its formation cannot be established through measurements of induced activity.

The great difficulty for the theory of β-ray emission, arising from the fact that potassium, in spite of its very long life, emits fairly hard β-rays of a mean energy of about 5×10^{5} e.v., has been discussed repeatedly. The discrepancies between theory and experiment would be somewhat lessened if it could be shown that the natural radioactivity of potassium is due to K^{40}, but this difficulty would still remain. It is of interest to note in this connexion that the artificially produced isotope of potassium 42, though having a similar period to thorium B, emits β rays of more than ten times greater mean energy than the latter. Also, the nucleus of this potassium isotope is thus emitting much harder rays than members of the radioactive disintegration series of similar period.

Absorption of Cosmic Particles in Copper and Lead

BY the method of the coincidences between three Geiger-Müller counters of 2.5 cm. diameter and 25 cm. effective length, disposed as in Fig. 1, I have carried out comparative measurements of absorption of the hard component of cosmic particles in copper (atomic weight $(A) = 63.57$, atomic number $(Z) = 29$) and in lead ($A = 207.20$, $Z = 82$). Lead screens (altogether 9 cm.) were arranged permanently between the counters, in order to exclude softer particles.

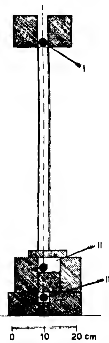

FIG. 1.

The absorbing screens, made of bars of surface area $2.5 \text{ cm.} \times 30 \text{ cm.}$, were interposed between the first and second counter; they had the same mass per cm.^{2} of 575 gm./cm.^{2}; the bars of lead were arranged in such a way as to occupy altogether the same height as the copper screen.

The triple coincidences were recorded by an automatic device[1], the resolving power of which, determined according to the double chance-coincidences, was 6×10^{-4} sec.; with this resolving power the expected number of triple chance-coincidences is 0.08 an hour.

The results given in Table 1 were obtained by alternating regularly the measurements taken without absorbing screen between the counters with those taken with the screens of copper and lead.

In the course of these measurements, the triple coincidences with the middle counter displaced laterally 3.2 cm. were also recorded in order to test the reliability of the method. Table II shows that not more than about a tenth of coincidences observed in the preceding case can be attributed to primary particles scattered by the screens or to secondary ones generated near the counters.

From the results reported in Table I there does not appear to be any difference, within the limit

of experimental errors, between the absorption of cosmic particles filtered through 9 cm of lead, in copper and lead, the mass per cm.² of the screens being equal. This absorption in 575 gm./cm.² is (37·6 ± 3·2) per cent.

TABLE I. Counters in line

	Permanent screen of 9 cm. of lead	Copper (575 gm./cm.²)	Lead (575 gm./cm.²)
Time observation (hours)	300·00	300·00	300·00
Triple coincidences observed	962	608	601
Triple coincidences per hour	3·206 ± 0·103	2·002 ± 0·082	2·000 ± 0·081

If the absorption were proportional to the number of electrons per cm.², the values of the absorption for the two screens of equal mass per cm.² should be in the ratio of $(Z/A)_{Cu}/(Z/A)_{Pb} = 0·87$; that is, a difference of 13 per cent would be expected. The measurements reported (as, indeed, others carried out on the absorption of particles of lower range[2]) do not reveal such difference. It appears therefore that the absorption may be rather connected with the mass per cm.² than with the number of electrons per cm.²: however, the statistical error of measurements, which amount to 8·83 per cent in comparison between the absorption of copper and lead, does not make this quite certain.

TABLE II. Middle counter displaced

	Permanent screen of 9 cm. of lead	Copper (575 gm./cm.²)	Lead (575 gm./cm.²)
Time of observation (hours)	100·00	103·93	101·62
Triple coincidences observed	42	26	22
Triple coincidences per hour	0·420 ± 0·066	0·250 ± 0·049	0·217 ± 0·046

What is certain, however, is that there does not exist for the absorption of the cosmic particles any marked dependence on the atomic number of the absorbing screen of the kind of that which has been found[3] for the absorption of the shower-producing radiation.

I beg to express my thanks to Prof. B. Rossi, who advised me to make this research.

Terrestrial Magnetism and Cosmic Rays

IT has been shown by several observers within the last few years that the ionisation caused by cosmic radiation, when reduced to the same barometric pressure, is not constant. In addition to a very small regular diurnal variation, the existence of which has been proved by continuous registration over a period of three years at 2,300 metres above sea-level[1], much larger and irregular variations have been found by different observers ("Schwankungen zweiter Art", as they were termed by A. Corlin). These are clearly perceivable when, for example, hourly observations of the cosmic ray intensity (or even the daily mean values) are reduced to standard pressure. At the Hafelekar Observatory in the Tyrolean Alps (2,300 m.) the daily average intensities may differ by so much as 0·10 *J*, that is, by 4 per cent (total ionisation with complete lead screen 10 cm. thick on all sides of the apparatus amounting to about 2·80 *J*). With apparatus unscreened from above, even larger variations may occur.

The so-called latitude effect of the cosmic radiation suggests a possible explanation of these irregular 'variations of the second kind', for W. Messerschmidt[2] has found that these irregular variations, as observed in a three-month series by the Hoffmann standard apparatus in Halle (Germany), were related to simultaneous variations of the horizontal intensity of the terrestrial magnetic field; a decrease of the latter seemed to cause an increase of the daily average cosmic ray ionisation, and vice versa.

We thought it worth while to investigate whether a similar relationship holds also in our observations at the Hafelekar. In order to eliminate the influence of the regular daily variations, we calculated the average cosmic ray intensity for each day of the year 1933 on which at least eighteen hourly observations were registered. Our observations were carried out partly with a lead screen of 10 cm. thickness on all sides of the apparatus, and partly with the screen underneath and on the sides but not on top. The former were made as a rule from the 1st to the 10th and from the 21st to the end of each month, the latter from the 11th to the 20th, according to an agreement with several colleagues abroad who were taking similar observations of the cosmic ray intensity in different places, ranging from lat. 68° N. to lat. 35° S.

The mean horizontal intensity *H* of terrestrial magnetism was calculated for each day from registrations of the Terrestrial Magnetic Station, Vienna-Auhof, by the formula

$$H = \frac{1}{24}(h_0 + 2h_2 + 2h_4 + 2h_6 + \ldots + h_{24}),$$

where h_0, h_2, etc., denote the observed magnetic intensities at 0^h, 2^h, 4^h, etc. These data were kindly placed at our disposal by Prof. Wilhelm Schmidt, director of the Meteorologische Zentralanstalt, Vienna.

Diagrams were then drawn for each 10-day and 20-day interval, showing the variations of the cosmic ray intensity (*a*) with complete screening (10 cm. lead on all sides), and (*b*) with no lead on top of the apparatus, with the variations of the average horizontal magnetic force from day to day. The latter varied between 20,470 γ and 20,530 γ, while the maximum of the cosmic ray fluctuation in case (*a*) amounted to about ± 0·05 *J*. (average 2·80 *J*.), in case (*b*) to ± 0·06 *J*. (average 4·6 *J*.), in the course of one year.

From the diagrams we were unable to obtain unambiguous evidence of any connexion between the variations of the horizontal component of the earth's magnetic field and of the cosmic ray intensity. There were even periods of several days in which an increase of the horizontal magnetic intensity was accompanied by an increase of the ionisation of the cosmic rays.

We therefore thought it best to calculate the correlation coefficients (*r*) between the daily means

of the cosmic ray ionisation and the horizontal magnetic intensity This was done using Charlier's method[3] Taking all observations of the year 1933 (eleven months, since in April no observations were taken) we obtained the following values

Case (*a*) (10 cm lead screen on all sides)	$r = -0{\cdot}12$		(January to December 1933)
Case (*b*) (no lead screen on top of apparatus)	$r = -0{\cdot}28$		

The negative values of r indicate that, on the whole, an anti-parallelism between the two magnitudes does exist, in concordance to W Messerschmidt's results. The numerical values of r are very low, therefore we must conclude that the relationship is rather slight

It is remarkable, however, that if we exclude the first three months of 1933, in which several slight alterations of our Steinke apparatus had to be made, we obtain a much better correlation

Case (*a*) (10 cm lead on all sides)	r 0·19		(May to December 1933)
Case (*b*) (no lead screen on top of apparatus)	$r -$ 0·57		

The correlation in case (*b*) is very good, thus indicating that the soft components of the cosmic radiation entering the apparatus when it is not screened from above are more influenced by variations of the horizontal intensity, and this is what is to be expected

We conclude that our observations indicate that the so-called 'variations of the second kind' of the cosmic radiation are partly due to variations in the opposite sense of the horizontal component of the earth's magnetic field

Radioactivity of Potassium

FERMI failed to detect induced β-radioactivity with calcium bombarded by neutrons, and this fact has been attributed[1] to the existence of a closed neutron shell in the calcium nucleus. We suggest alternatively that the failure to detect radioactivity may constitute a proof that the source of the natural radioactivity of potassium is the isotope $_{19}K^{40}$ of such small abundance that it cannot be detected by means of the mass-spectrograph

Aston's work indicates that $_{20}Ca^{40}$ is by far the most abundant calcium isotope, the ratio of $_{20}Ca^{40}$ to $_{20}Ca^{44}$ being 70 to 1, the other isotopes of mass number 42 and 43 being present in very small amounts. Thus by far the greater number of neutrons will interact with $_{20}Ca^{40}$ and it seems reasonable, therefore, to suggest that any radioactivity induced in isotopes other than $_{20}Ca^{40}$ will be too slight to be detectable. In addition, Fermi has definitely detected proton emission following neutron capture with $_{12}Mg^{24}$, $_{13}Al^{27}$, $_{14}Si^{28}$, $_{15}P^{31}$, $_{16}S^{32}$, $_{24}Cr^{52}$ and $_{30}Zn^{64}$, and of these seven isotopes five have even atomic number It therefore appears likely that the following reaction occurs when calcium is bombarded with neutrons

$$_{20}Ca^{40} + n \rightarrow {}_{19}K^{40} + p \uparrow .$$

As a result of such an action, only a very small number of radioactive potassium nuclei could be produced, and assuming $_{19}K^{40}$ is the source of the natural radioactivity of potassium, the long life of this isotope explains why no disintegrating electrons were observed

Radioactivity Induced by Neutrons

AMALDI, d'Agostino and Segrè[1] report that, using neutrons from a radon - alpha particle - beryllium source, they have induced an activity in indium of a very short half-life period (13 sec) and also one of half-life period of about one hour (54 min)

Our own unpublished observations on indium show the one hour period and a longer period of several hours (estimated at 3½ h). If indium is irradiated in air these two periods show strong initial intensities of the same order of magnitude, but if it is irradiated in water, the one hour period is so strongly reinforced that it overshadows the long period and may thereby prevent its detection Thus three periods appear to exist for indium, and the two shorter ones of these are reported[2] to be strongly water sensitive

Indium has two known isotopes[3] (mass numbers 113 and 115, the ratio of their abundance being less than one to ten). It has an odd atomic number and since, apart from the isolated case of hydrogen, there is no precedent for such an element having more than two isotopes, we tentatively assume that no further stable indium isotope is involved. Accordingly we conclude that one of the two indium isotopes is activated with more than one period

The question arises whether the observed periods can be interpreted on the basis of the primary processes which have so far been recognised in the Fermi effect. These recognised processes are (*a*) capture of the neutron by the nucleus (all cases so far investigated were reported to be water-sensitive), (*b*) ejection of a heavy positively charged particle—a proton or an alpha particle—from the nucleus (all cases so far investigated were reported not to be water-sensitive) Some isotopes of lighter elements are known to be activated with two or three periods, the ejection of a proton or an alpha particle being quite a common process for elements lighter than zinc (atomic number 30) No such processes have so far been observed for elements heavier than zinc.

In the circumstances the Fermi effect of indium (atomic number 49) seems to deserve further investigation, for which adequate instruments of observation are not at present at our disposal.

Induced Radioactivity produced by Neutrons liberated from Heavy Water by Radium Gamma-Rays

WORKING in this laboratory, Szilard and Chalmers[1] have shown that neutrons are liberated from beryllium irradiated by radium gamma-rays, and that they are capable of inducing radioactivity in a number of elements. Previously, Chadwick and Goldhaber[2] had reported that, using an ionisation method, they had observed the liberation of protons from heavy hydrogen which was irradiated by gamma rays from thorium C.

In the light of these observations, and having regard to possible biological applications of heavy water, it is of interest to determine whether the neutrons presumed to be liberated by the gamma-ray disintegration of heavy hydrogen can activate other elements.

We have succeeded in observing the radioactivation of iodine and bromine which had been bombarded by the neutrons liberated from heavy water irradiated by radium gamma-rays. In one series of experiments we used 10 c.c. of heavy water of 30 per cent concentration, and irradiated it with gamma-rays from 150 mgm. of radium filtered by 1 mm. of platinum. The heavy water almost completely filled the space between the double walls of a glass container similar in construction to a diminutive cylindrical Dewar vessel. The radium occupied the central cavity of the container, which was immersed in 400 c.c. of ethyl iodide.

After irradiation, the radio-iodine was precipitated and removed from the ethyl iodide by the method of isotopic separation described by Szilard and Chalmers[3], and its activity measured on a Geiger-Muller β-ray counter. Using the quantities above mentioned, the counter recorded an average of 110 impulses in 5 minutes, whereas the control experiments carried out with 10 c.c. of ordinary water contained in a duplicate vessel gave 55 impulses against a normal 'background' of 30-35 impulses in 5 minutes. We attribute the difference in count between the normal 'background' and the control experiments with ordinary water to primary neutrons emitted by the source.

A similar series of experiments, in which 300 c.c. of bromoform was substituted for the ethyl iodide, gave strictly comparable results with radio-bromine to those obtained with radio-iodine. We conclude that neutrons emitted from heavy water irradiated by radium gamma-rays are capable of inducing radioactivity in iodine.

Spectrum of Ordinary Hydrogen (H_2)

I HAVE recently found several systems of bands in which the electronic transitions are from new upper states of H_2 down to the singlet state generally denoted by ^1X. These band systems are of importance and interest for a variety of reasons.

I gather that there is no general agreement as to what the electronic configuration of the final state ^1X is, but I have put forward what I believe strong reasons for thinking it to be the $1s\sigma 2s\sigma\,^1\Sigma_g$ state which otherwise would, quite unaccountably, be missing. Hitherto, our knowledge of ^1X, derived from the analysis of the $^1X \rightarrow 2p\,^1\Sigma$ system, has been very meagre except at the vibrational levels $v = 1$ and 2. These levels have a very irregular rotational structure and so also had the $v = 3$ level according to the old analysis.

This has generally been supposed to be due to uncoupling, which is impossible if the state is $1s\sigma 2s\sigma\,^1\Sigma$, or to some other type of perturbation. I have recently repeated the former analysis of the $^1X \rightarrow 2p\,^1\Sigma$ system and have found an error at the $v' = 3$ level and some new lines. These changes make the rotational structure of the $v' = 3$ level quite regular as H_2 levels go. As a result of the analysis of the new systems ending on ^1X, I have found what I believe to be the $v = 0$ level of this state. It has a quite regular rotational structure and is about what one would expect *a priori* for $1s\sigma 2s\sigma\,^1\Sigma$, so that the most serious objection to the identification of ^1X with $1s\sigma 2s\sigma\,^1\Sigma$ has now disappeared. The cause of the rotational irregularity at the $v = 2$ and 3 levels is still a mystery. The difficulty about attributing it to a perturbation is that there is no known state, and so far as can be foreseen no possible state, which could be in the position and have the other properties theoretically necessary to cause a perturbation.

The strength of the new systems, which are weak, lies mainly along the diagonal axis in each case. So far, three systems seem to have emerged definitely, but there are indications of the existence of others. The upper states of the three I call provisionally ^1D, ^1R and ^1U. The analysis of these has gone far enough to enable some definite, though preliminary, statements to be made about them.

The system $^1D \rightarrow {}^1X$ lies in the infra-red around 8000 A. I believe that the upper state ^1D is the same as the D state of Hopfield, to which he found strong transitions up from the ground state in the absorption spectrum of H_2. At least if my interpretation[1] of Hopfield's data be accepted, they lie close together and have similar properties. An analysis of the $v = 2$ and 3 levels of ^1D (I have not yet found the $v = 0$ level and the $v = 1$ level is not very secure) gives the following approximate electronic constants: ν_e (depth from the ground level of the molecular ion) 11267 wave numbers, Rydberg denominator 3·12, fundamental frequency (ω_0) 2300 wave numbers. The corresponding quantities for Hopfield's D state which I derived from his absorption data are: ν_e 11560, *R.d.* 3·08, ω_0 2257, $x\omega_e$ 59.5. These data also involve an extrapolation from higher but different vibrational levels down to the $v = 0$ level, so that exact agreement is not to be expected. I think that ^1D is $1s\sigma 3p\pi\,^1\Pi_u$, but the possibility that it might be $1s\sigma 3p\sigma\,^1\Sigma_u$ is not yet absolutely excluded.

The system $^1R \rightarrow {}^1X$ lies around λ5900 A. The ν_e of ^1R is about 6400 giving a denominator of 4·14, ω_e is about 2230 and $x\omega_e$ about 60. I think ^1R is $1s\sigma 4p\pi\,^1\Pi_u$, but here again $1s\sigma 4p\sigma\,^1\Sigma_u$ is also possible. $^1U \rightarrow {}^1X$ lies around λ5400 A. The approximate numerical data for ^1U are $\nu_e = 4900$ wave numbers, *R.d.* = 4·74, ω_e about 2220 and $x\omega_e$ about 45. I think this state is most likely to be $1s\sigma 5p\sigma\,^1\Sigma_u$, but there are some lines about which look like Q branches, so it may be

a Π state. In that case it may be either $1s\sigma 5p\pi\,^1\Pi_u$ or $1s\sigma 5f\pi\,^1\Pi_u$, but I think it certain that it has one unexcited electron ($1s\sigma$). All the other properties of the new upper states are in agreement with what would be expected for these assignations

Fluorescence of Fluorite and the Bivalent Europium Ion

EXPERIMENTS conducted in this Institute[1] had led to the conclusion that the blue fluorescence of fluorite excited by filtered ultra-violet light is due to traces of europium under the influence of radioactive substances, and that a yellow-green fluorescence which some fluorites show at the temperature of liquid air—especially those from acid magmatic rocks—is, in the same way, due to ytterbium As these rare earths are those most readily obtained in the bivalent form[2], as further the reducing action of Becquerel rays is well known, and as the blue fluorescence can also be obtained in CaF_2 containing europium, simply by reduction through heating, the hypothesis was put forward that these broad 'radio-photofluorescence' bands are to be ascribed to the *bivalent* forms of the rare earths

Through the courtesy of Prof G Jantsch, of Graz, we are now able to *prove* this hypothetical assumption in the case of europium Prof Jantsch kindly lent us preparations, made in the Institut für anorgan. chem Technologie und analyt Chemie of the Technische Hochschule, Graz, of pure $SmCl_2$, $SmCl_3$, $EuCl_2$ and $EuCl_3$, of which the last shows, when excited by filtered ultra-violet light, a brilliant purplish pink fluorescence, as already noticed by Prof. Jantsch. Spectrograms of this fluorescence, taken by Miss B. Karlik in this Institute, show *a broad band in the blue, identical with the well-known fluorite band*, and in the red a rather narrow line at 690 mμ, as well as a diffuse band with a maximum at about 630 mμ, which strikingly resembles a red band shown by some fluorites but also by synthetic 'pure' CaF_2 after suitable heat and radium treatment. Whilst there can be no more doubt about the blue fluorite band being due to bivalent europium, the question if the red band in fluorite is also to be attributed to minute traces of this substance must form the subject of further investigations

$EuCl_3$ and $SmCl_3$ show no fluorescence, the latter perhaps because of its deep black colour $SmCl_3$ fluoresces orange[3], with lines at 603 5 and 598 5 mμ It is to be hoped that these observations may also furnish new clues to the atomic structure of the rare earths A detailed report will be presented to the Vienna Academy of Sciences

Quasi-Crystalline Structure of Liquids and the Raman Effect

IT is known that at the scattering of light in liquids a continuous spectrum appears[1] around the primary line on both sides to a distance of about 15–20 A This effect is usually referred to as 'wings'

These wings are generally ascribed to unresolved rotation Raman lines It seemed to one of us[2] more probable that the appearance of wings is connected not with rotation of molecules but with a new type of frequency change of the scattered light found by one of us[3]. For several years the wing phenomenon has been systematically investigated in our laboratory in various compounds and in different experimental conditions One of us (E G) has investigated the influence of temperature on the wings It might be expected that the raising of temperature would cause a broadening of wings, if they were really due to rotations of the molecules, but no difference could be found in the breadth of wings given by xylene at $t_1 = 15°$ C. and $t_2 = 160°$ C ($T_2/T_1 - 1\ 5$) Only a slight increase of the intensity of the wings just near the primary line could be noticed With diphenyl ether, $(C_6H_5)_2O$, which could be heated to 250° C ($T_2/T_1 \approx 2$), we have obtained similar results, the only difference being that the increase of intensity just near the primary line was more pronounced Therefore we can conclude that the wings consist of two different parts behaving differently on heating an inner part (about 20 cm.$^{-1}$) in the closest vicinity of the primary line, and an outer and much greater part The absence of broadening of the second part on heating is opposed to the rotation hypothesis. This part behaves on heating like vibrational Raman lines and could be attributed to the loosely bound vibrations

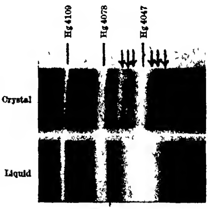

FIG 1 Raman effect of crystalline and liquid diphenyl ether

With the view of putting the vibrational and rotational hypothesis to the test, we have investigated the Raman effect in a crystal of diphenyl ether, and have obtained most interesting results. Instead of wings, we obtained on their position four lines lying on both sides of the primary line (Stokes and anti-Stokes lines). Some of the lines, marked by arrows, are clearly seen in Fig. 1 These lines correspond to infra-red frequencies of $\nu_1 = 21$ cm.$^{-1}$, $\nu_2 = 39$ cm.$^{-1}$, $\nu_3 = 69$ cm.$^{-1}$ and $\nu_4 = 100$ cm.$^{-1}$. These new lines are the vibrational Raman lines and not the rotational ones, for the following reasons:

(1) The distances between the lines are unequal and of different order of magnitude from that determined by the moments of inertia of the diphenyl ether molecule

(2) The intensity of the lines $\nu_1 = 21$ cm $^{-1}$ and $\nu_4 = 100$ cm $^{-1}$ is greater than that of $\nu_2 = 39$ cm $^{-1}$ and $\nu_3 = 69$ cm $^{-1}$ When the crystal is melted, these lines broaden into a continuous spectrum (wings), while other Raman lines do not undergo any marked change It seems, therefore, that we can ascribe the former lines to vibrations characteristic of the crystal lattice and the latter to molecular vibrations The fact that the former lines do not disappear in the liquids shows that apparently some elements of the crystal lattice remain, although deformed, also in the liquid state

A more careful investigation of the Raman spectrum of liquid diphenyl ether showed that a broad diffuse maximum of intensity appears in the region of the wings corresponding to the strong line $\nu = 100$ cm $^{-1}$ in the crystal On raising the temperature to 250° C, this maximum broadened until it could not be noticed against the continuous spectrum of the wings.

All these observations are in good agreement with the theory of the quasi-crystalline structure of liquids often discussed in connexion with the diffraction of X rays[4]

In some degree the appearance of the wings is characteristic for most, if not for all, liquids. There is no reason to expect that in other liquids (such as benzene), this phenomenon has a different origin from that in diphenyl ether Thus, generalising the above results, we may say

(1) The usually accepted explanation of the wings is not correct This phenomenon is principally due not to the rotational but to the vibrational Raman effect A slight asymmetry in the intensity distribution on the red and the violet side[5] as well as the dependence on the primary frequency[6] is easily explained

(2) The part of the wings adjacent to the primary line, which grows in intensity with rising temperature, is probably a prolongation of the continuous spectrum observed[7] between the components of the Rayleigh line by instruments of great resolving power. Perhaps for this part of the wings the rotation hypothesis is valid, though it may be connected also with Debye heat vibrations

(3) Our experiments give new facts in support of the theory of the quasi-crystalline structure of liquids They indicate the possibility of examining this problem by means of the Raman effect

At the present time, detailed investigations of the wings from this new point of view are in progress in our laboratory with different compounds in the liquid, crystal and gaseous states

Identity of the Growth-Promoting and Root-Forming Substances of Plants

In a recent brief communication on the chemical nature of the root-forming hormone of plants[1], the following evidence was brought forward

(1) The hormone is an organic acid, dissociation constant about $10^{-4.5}$, the activity of which is readily destroyed by oxidising agents

(2) The hormone has about the same solubilities in various organic solvents, and distils in the same temperature range *in vacuo*, as the auxin, or growth-promoting hormone, obtained from *Rhizopus suinus*

(3) The crystalline auxin preparations prepared by Kögl and co-workers from urine[2] show root-forming activity, and their activity is destroyed by oxidising agents, when the destruction is partial, the root-forming and growth-promoting activities are destroyed to the same extent

The evidence thus points to the identity of the two hormones, but on account of the inconstancy of the ratio of the two kinds of activities in various preparations and for other reasons, the matter was left open

It has since been found by Kögl, Haagen-Smit and Erxleben[3], that one of the active growth-promoting hormones present in urine is identical with β-indolyl-acetic acid We have, therefore, prepared this substance synthetically, and find it to be fully active in promoting root formation The possibility of an active impurity in the products obtained from natural sources scarcely arises in the case of a pure synthetic compound, and no doubt therefore remains that, of the factors promoting root formation, this one is identical with that which gives rise to growth by cell elongation The pure substance has an activity of from 7 4 to 28 × 10^4 root units per mgm, and a growth-promoting activity of 31 × 10^4 growth-stimulating units per mgm, hence a ratio root units to growth-stimulating of from 0 2 to 0 7 This agrees satisfactorily with the figures previously quoted by us for the crystalline auxins of Kögl and co-workers[1], so that the root-forming activity of these substances could not have been due to traces of impurities either It may be noted that the ratio between our growth units and those of the Utrecht workers, previously deduced on theoretical grounds[4], would give β indolyl-acetic acid an activity of 2 5 × 10^7 *Avena* units (A E) per mgm, compared with 1 to 2 × 10^7 A E per mgm. given by Kögl and co-workers

The fact that two such different functions as the formation of roots on cuttings and the growth of tissues by cell elongation should be brought about by the same specific substance raises interesting questions of mechanism, particularly since all three of the substances are about equally active in both functions.

The homologues of β-indolyl-acetic acid, namely β-indolyl-propionic and indole-β-carboxylic acids, are without activity in root formation, they were correspondingly shown to be inactive in growth promotion by Kögl, Haagen-Smit and Erxleben[3]. Our own preparations and tests confirm the results of the latter workers in respect of growth promotion. Indole itself is also inactive. The propionic derivative, which was a commercial product, showed, even after two recrystallisations, slight growth-promoting activity in concentrated solutions, due doubtless to the persistence of traces of its lower homologue. The activity, which was less than 0·2 per cent of that of β-indolyl-acetic acid, was still further reduced on again recrystallising.

The test for root-forming activity, using pea cuttings, has been described by Went[6]. The β indolyl-acetic acid was prepared by the method of Majima and Hoshino[6]. The indole-β carboxylic acid was prepared by direct combination with carbon dioxide as described by Zatti and Ferratini[7]

Starvation and Regenerative Potency in *Dendrocoelum*

THE regenerative potency of Planarians may be depressed in several ways, for example, by irradiation (Wiegand, 1930, and others), or by repeated regeneration of the head-region (10 days after a previous amputation Sivickis, 1931) This has been interpreted by some authors as due to a reduction in the amount of formative material available, by others as due to alterations in the general metabolism of the body and the degree of differentiation of the tissues involved (Sivickis)

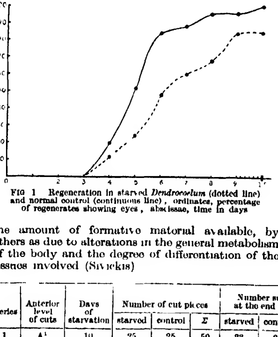

FIG 1 Regeneration in starved *Dendrocoelum* (dotted line) and normal control (continuous line), ordinates, percentage of regenerates showing eyes, abscissae, time in days

Series	Anterior level of cuts	Days of starvation	Number of cut pieces			Number survived at the end of expt			Number of regenerations			Delay in time of completion of regeneration
			starved	control	Σ	starved	control	Σ	starved	control	Σ	
1	A[1]	10	25	25	50	23	22	45	23	22	45	> 24 hours
2.	A[1]	8–10[3]	25	25	50	21	23	44	18	23	41	24 hours
3	B[2]	8–10[3]	25	25	50	16	16	32	14	16	30	> 24 hours
4.	A[1]	20	25	25	50	25	25	50	21	25	46	> 24 hours
Summary			100	100	200	85	86	171	76	86	162	

[1] Closely posterior to eyes [2] Midline between eyes and pharynx [3] Judged only by the colour of the intestine

To test these ideas, experiments were undertaken on the effect of starvation For this purpose, the abundant species *Dendrocoelum lacteum* is very convenient, since the degree of starvation is reflected in the colour of the animals, the dark gut contents showing through the translucent white body

Well-fed stocks of defined degrees of starvation were taken, their heads amputated, and observation continued for 15 days (for details see Sivickis) The appearance of eyes were taken as the criterion of successful regeneration. Four series, differing slightly in detail as to level of cut, degree of starvation and temperature, have given concordant general results, in that the regenerative potency was always lower in the starved stocks, regeneration being delayed, and (in three of the four series) the percentage of non-regenerating specimens increased (see Fig 1 and table) The proportion of non-regenerating specimens for all series was 0 per cent for controls and 10 per cent for the starved stocks, although the mortality rate of the latter was not increased at all

Starvation thus has the same effect on regeneration as radium treatment or as previous head-amputation (see especially Sivickis, Fig 3) This indicates with a high degree of certainty that the reduction of regenerative potency in all three cases is due to a reduction in the amount of formative material available for regeneration. Studies on the histology of starvation (for example, Schultz, 1904, Stoppenbrink, 1905, Berninger, 1911, Bartsch, 1923) clearly show that such material is used up during starvation, and the work of Steinmann (1925, 1926) shows the close resemblance of the histological changes observed in starvation and in regeneration

Duration of Life-Cycle of the Death-Watch Beetle

So far as published accounts record, the death-watch beetle (*Xestobium rufovillosum*, De G) has never been bred in the laboratory and no study has, therefore, been possible of the factors affecting its development and the duration of its life-cycle In discussing the treatment of timber roofs attacked by *Xestobium*, Lefroy[1] summarised in 1924 the knowledge of the biology of the insect up to that time and pointed out how little was known of its life-history and habits

During the past four years, a study of the life-cycle and duration of the different stages of the insect has been in progress at the Forest Products Research Laboratory, and in the course of this work the beetle has been reared from egg to adult The results of this investigation—a full account of which will be published elsewhere—lead to the general conclusion that, given a suitable timber, for example, oak or willow, the

length of the life-cycle of *Xestobium* depends upon . (*a*) condition of the timber with reference to fungal decay ; (*b*) moisture content of the timber , (*c*) temperature conditions

For example, the insect has been reared in the remarkably short period of 11 months in willow in an advanced stage of decay at moisture content of 18–20 per cent (based on dry weight of wood) and at a temperature of 20°–25° C On the other hand, under similar conditions of temperature and humidity, but with wood in a very much less advanced stage of decay, the beetle has not yet completed its development after a period of 22 months Furthermore, at temperatures of 20°–25° C , the duration of the life-cycle of the insect reared in oak sapwood, in varying stages of decay, and at moisture contents less than 18 per cent, occupied 28–30 months and longer Under out-of door conditions in decayed oak and willow, it has been prolonged still further and has not yet been completed

Now that it is possible to breed *Xestobium* in the laboratory, further work is in progress on the relationship between the type and extent of fungal decay in timber and its susceptibility to attack The results so far obtained, however, lend support to the view that the development of *Xestobium* in buildings is extremely slow unless conditions unusually favourable for rapid decay of the timber are present

Transformations of Isomeric Sugars

DEFINITE evidence is now available of the correctness of the views expressed in our former letter on this subject[1], as, in a smooth series of reactions, we have succeeded in converting *d* glucose into *d*-galactose and *l*-gulose The two transformation sugars have been isolated separately and identified

Starting from α methylglucoside, an anhydro ring was formed between positions 3 and 4 of the glucose chain as a result of consecutive reactions which gave as the end product an amorphous 2-acetyl 3 4-anhydro 6-trityl α-methylhexoside After opening the anhydro ring, two distinct acetone derivatives were obtained, namely

(*a*) A monacetyl monacetone methylhexoside, m p 101°–102°, $[\alpha]_D$ + 127 3° in chloroform.

(*b*) A monacetyl monacetone methylhexoside, m p 176°–178°, $[\alpha]_D$ + 76·8° in chloroform

On deacetylation, the compound (*a*) gave a theoretical yield of a monacetone methylhexoside, m p 109°–110°, $[\alpha]_D$ + 147 2°, from which, on partial hydrolysis, α-methylgalactoside was obtained which showed correct melting point and mixed melting point and a specific rotation of + 175 5° in water From this, in turn, *d*-galactose was isolated and identified by determination of the optical activity and by conversion into the phenylosazone.

In a parallel series of reactions, the isomeride (*b*) gave a monacetone methylhexoside, m p 132°–133°, $[\alpha]_D$ + 88·5° in chloroform On complete hydrolysis to the parent sugar, the rotation became lævo, $[\alpha]_D$ − 17·9°, and as the phenylosazone melted at 156°, the product was evidently *l*-gulose The scission of the 3 : 4-anhydro ring in glucose may give four possible products . *d*-glucose, *d*-allose, *d*-galactose and *l* gulose, and doubtless all are present Of these only *l*-gulose is lævorotatory, and its isolation together with *d*-galactose is of special interest in view of the relationship of these hexoses with ascorbic acid and lactose respectively We are accordingly extending our work with the object, *inter alia*, of converting maltose into lactose

Luminous Night Clouds over Norway in 1933 and 1934

As reported in a letter to NATURE[1] large masses of noctilucent clouds were seen over southern Norway in the night of June 30–July 1, 1934 From three of my aurora stations I got a series of simultaneous photographs of these clouds The plates have now been measured, and the results will soon appear in *Astrophysica norvegica* The following points from this paper may be of interest

Seven pairs of plates gave the following 41 heights in kilometres 82, 83, 82 5, 84, 84, 82 5, 82·5, 82, 83 5, 82, 82, 85, 82 5, 81, 82, 84, 81, 80 5, 81, 82, 81 5, 81, 81 5, 82 5, 82 5, 82, 82, 82 5, 83, 82, 78, 82, 82, 83 5, 82, 82, 81, 83·5, 82 5, 83, 81 The mean, 82·2 km , agrees very well with the mean value 82 08 km found by Jesse from observations in the years 1889 91 It also agrees with my own measurements from 1932, which gave 81 4 km

The velocity of the clouds was 80–83 metres a second from east to west A series of waves with their crests orientated north and south appeared, the distance between successive crests being 6–9 km

As observed in 1932, sun rays passing nearer to the earth's surface than about 30 km do not make the clouds shine This may suggest that the clouds are chiefly illuminated by ultra violet rays

From different people I have received observations and photographs of luminous clouds on the following nights 1933 July 4–5, 7–8, 9–10, 19–20, and August 9–10, 23–24 1934 June 30–July 1, July 5–6, 6–7, 16–17, 17 18, 18–19, 30–31, July 31–August 1, August 7–8

A very interesting case is the occurrence of such clouds over central Norway on July 19–20, 1933, because similar clouds were observed 33 hours later over Canada[2], coming from the east-north-east, which corresponds to a drift of 48–57 metres a second, if the clouds had drifted from Norway to Canada For further details I must refer to the complete paper which is in print

In conformity to the opinion expressed by Vestine in his paper mentioned above, it seems to me that the luminous night clouds are likely to consist of cosmic dust coming from interplanetary space into the upper atmosphere in the same way as shooting stars and meteors The arguments in favour of this opinion are the following .

(1) The occurrence of luminous night clouds after the great Siberian meteor (1908), also adduced by Vestine as an argument in favour of a cosmic origin of the clouds.

(2) The occurrence of the clouds in the months of June and July, with a maximum near the end of June, which is comparable with the fact that shooting stars appear at certain fixed dates of the year. The reported occurrences of such luminous clouds in the

summer months of southern latitudes, however, seems difficult to explain as the result of the same swarm of cosmic dust

(3) The greatest intensity of the phenomenon after midnight is then intelligible in the same way as the analogous maximum of frequency shown by shooting stars after midnight, due to the fact that the morning side precedes in the earth's motion round the sun

(4) As shown by Vestine, there are more coincidences between luminous night clouds and meteoric showers and comets than between these clouds and volcanic eruptions, which points to a cosmic origin

(5) The blue-white colour points more to fine dust than to water drops and ice-crystals This was also pointed out by Vestine

(6) The sporadic occurrence of the clouds points to irregular precipitations of cosmic dust over limited areas, in particular on the side of the earth which precedes in its motion round the sun

Musical Atmospherics

THE characteristics of audio musical atmospherics which are obtained when an audio amplifier is placed in a long line or aerial have been discussed from time to time[1] Messrs Burton and Boardman have given an account of their observations in which the musical atmospherics are considered to fall into two categories distinguished mainly by their duration and the frequency gamut covered The short musical atmospherics which occur only at night time, variously christened 'tweeks' or 'chinks' lasting 1/20–1/5 sec and covering a gamut of frequency 4,000 to nearly 1,600, can be adequately explained as the multiple reflections between the earth and ionosphere The more interesting long-duration audio atmospherics, variously called 'swishes', 'whistlers', *Pfeifone*, have received no adequate explanation although many suggestions have been offered I have maintained for some time that the effect is due to the dispersion of a pulse in the ionosphere, and a theory has been developed which accounts for the main characteristics of such audio atmospherics.

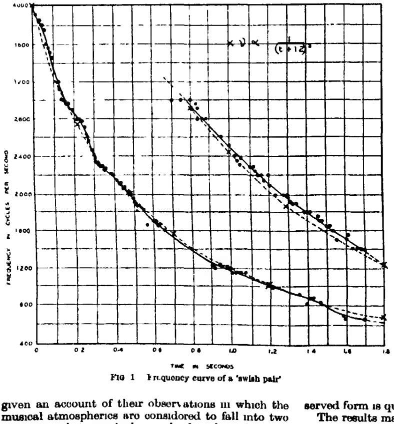

FIG 1 Frequency curve of a 'swish pair'

In this theory, a pulse originating in the lower atmosphere as a lightning flash, or more probably produced in the upper atmosphere by a burst of ions from the sun, produces a spectrum of electromagnetic waves which traverse the spherical channel formed by the ionosphere and are reflected at the polar regions

The theory supposes that it is possible that waves of such low frequency (between 400 c/sec and 4,000 c/sec) can traverse the densely ionised region of the ionosphere There are two alternative theories of the dispersion in an ionised region according as the Lorentz-Hartree correction is included or not, in which the refractive index is either

$$1 - \frac{\zeta}{1+\frac{1}{2}\zeta} \text{ or } 1-\zeta, \text{ where } \zeta = \frac{Ne^2c^2}{\pi m\nu^2}$$

(No magnetic field)

If the former is correct, then for frequencies less than the critical frequency ν_0 (over dense medium), $\nu_0^2 = Ne^2c^2/\pi m$, the ionosphere is completely lacking in transparency for either ordinary or extraordinary ray whatever the direction and magnitude of the earth's magnetic field If the latter is correct, then the ionosphere is transparent to the extraordinary ray if $\nu < \nu_1 = eH/2\pi m$ and if the direction of the ray is not too nearly perpendicular to the earth's magnetic field Clearly the theory proposed is only possible if the Lorentz-Hartree correction is neglected A consequence of the theory is that the frequency of the whistler at any time t after the initial pulse should be proportional to $1/t^2$ so long as all the waves traverse approximately the same path irrespective of frequency

Messrs Burton and Boardman have obtained a record shown in Fig. 1 of the frequency of a whistler as a function of the time The dotted curve shows the relation $\nu \propto 1/(t+1\cdot 2)^2$, where t is the time elapsed from the observed start of the whistler. The 1·2 sec. should then represent the time between the initial pulse and the start of the musical disturbance. (The initial impulse was not audible in this case but intervals of this order are often observed.) The agreement between the theoretical and observed form is quite close

The results may perhaps be considered as evidence (1) that the whistler is caused by the dispersion of a sudden pulse travelling through the ionosphere

(2) that the simple form of dispersion formula (without the Lorentz-Hartree correction) is correct for transmission in an unpolarised medium like the ionosphere.

This is the conclusion arrived at by Darwin[2] on theoretical grounds.

Over-Potential of the Hydrogen Isotopes

ALTHOUGH the separation of the two hydrogen isotopes which occurs on electrolysis must be closely connected with their over-potentials, no measurement of these has been published. A comparison of the deuterium over-potential with that of hydrogen can be of value in elucidating the general mechanism of hydrogen over-potential itself and, as part of an experimental investigation of this, measurements have been made on deuterium. In order to eliminate errors due to the resistance of the electrolyte and to violent gas evolution, it is essential that very low current densities should be used, and the electrolyte must be free from traces of oxygen or dissolved impurities. The over-potential measurements were made under conditions similar to those described in earlier papers[1], but it was a matter of some experimental difficulty to realise these with the small quantities of electrolyte available (1 c.c.). The results obtained with a mercury cathode in a 0·2 *N* sulphuric acid electrolyte are shown in Fig. 1.

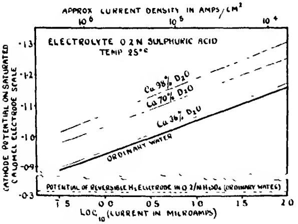

FIG. 1

It is apparent that both isotopes give the same linear relation between current density and over-potential, and that the slope of the line is nearly the same in each case[2] ($\alpha = -2·3\,RT\,d\log i/dV$ = about 0·5). The irreversible potential of the deuterium is, however, considerably higher than that of hydrogen (*c.* 0·13 volts more negative). For 100 per cent heavy water the difference would be slightly greater. (The over-potential is, strictly, the potential difference between an irreversible electrode and a reversible electrode working in the same electrolyte. Measurements made in this laboratory by Dr. K. E. Grew show, however, that the potential difference between a reversible deuterium electrode and a reversible hydrogen electrode is small.)

From these measurements it is clear that the over-potential difference between the isotopes is sufficiently great to explain the separation which occurs on electrolysis. From the curves we may calculate a possible separation factor under these optimum conditions. For example, at a cathode potential of $-1·05$ volts sat. cal.

$$\frac{\text{the rate of evolution of } H_2}{\text{the rate of evolution of } D_2} = \frac{9·23 \times 10^{-6} \text{ amp}}{0·668 \times 10^{-6} \text{ amp}} = \frac{13·8}{1}.$$

We have also measured the temperature coefficient of the deuterium over-potential and find that it is greater than for hydrogen, showing that the efficiency of separation will decrease as the temperature increases.

As would be expected, the actual separation factor observed during the preparation of heavy water is considerably less than the possible one suggested above. (It varies from *c.* 3 at a reversible electrode to *c.* 8[3,4].) Under the usual conditions of electrolysis, there are many factors such as high current density, high local temperature, concentration polarisation, low over-potential properties of the electrode surface, interchange, etc., all of which tend to lower the efficiency. The bearing of these results on the mechanism of over-potential will be discussed elsewhere.

It is with much pleasure that we express our thanks to Drs. A. and L. Farkas for analysing the heavy water and to Imperial Chemical Industries, Ltd., for a grant.

Fundamental Dimensions of μ_0 and K_0 in Electrical Science

THE recent work of committees both national and international upon the fundamental units and definitions in electrical science has shown that a considerable further step in advance, by removing difficulties, would result from the discovery of the dimensions of μ_0 and K_0, the magnetic permeability and electric permittivity or specific inductive capacity of the medium. Some writers have recommended that the dimensions of one of these should be chosen arbitrarily in order to get this simplification, the result of which would be that the difference in physical dimensions of the various quantities, when measured in electrostatic and electromagnetic units, would disappear. Difference in size of unit causes no confusion, but the difference in dimensions due to changing the scale of measurement has been a great cause of confusion.

Electrical science is based fundamentally upon the definitions of quantity of electricity e, magnetic pole m and electric current i. The definitions of these three quantities are given by the three equations:

$$\text{force} = ee'/K_0r^2 \;.\;.\; (1) \quad \text{force} = mm'/\mu_0r^2 \;.\; (2)$$
$$\text{and } i = de/dt \;.\;.\; (3).$$

In these equations, μ_0 and K_0 are dimensional constants the numerical value of which would depend upon the units of measurement, but their physical dimensions depend solely upon the medium In the historical development, i is, again, defined electrodynamically either by the action of a current upon a magnetic pole or upon another current, and the two systems of units are thus introduced with their different dimensions for each quantity

I am only concerned with the physical dimensions and not with the sizes of the units Let us assume that the symbols used contain their own units, just as is common practice in dynamics We have already defined i, and therefore there is no necessity to introduce another definition for it.

Ampère's fundamental equation in electrodynamics is given by

$$\text{force} = ii'\,ds\,ds'\,(1\cdot 5\cos\theta\cos\theta' - \cos\varepsilon)/A'r^2 \qquad (4),$$

representing the force between the elements ds, ds', distance r apart, carrying currents i, i'; θ, θ' and ε being respectively the angles between the elements and r and between the elements themselves, and A' is a dimensional constant Having already defined i, let us take this as an empirical equation

Maxwell states as a fact that an electric circuit is *equivalent* to a magnetic shell bounded by the circuit, a discovery which he ascribes to Ampère The physical meaning of this equivalence is explained by modern electronic theory, which ascribes all magnetic phenomena to the electronic orbits in the atoms, thus reviving a suggestion of Ampère's in 1820 that all magnetic phenomena might be due to electric currents round the particles of matter The molecular magnets of Ewing's useful theory are also thus accounted for.

The interpretation to be attached to the meaning of the word *equivalent* has a most important effect upon the science The interpretation adopted by standard practice is contained in the equation $mL = \mu_0 iL^2$, corresponding to the magnetic flux being μ_0 times the magneto motive force, or the current circuit and the magnetic shell are considered as cause and effect connected by the modulus μ_0 This interpretation leads to the present system having dual dimensions for each quantity, connected by $c^2\mu_0K_0 = 1$

I submit that, in the light of electronic theory, another interpretation of the phenomena and of the meaning of the word equivalent, is that the magnetic flux is part and parcel of the current and is only another partial aspect of the phenomena, and, just as in vortex motion we speak either of the vortex or its core, so in electromagnetism we may speak either of the magnetic flux or of its core i The result of such an interpretation is that each ampere turn of magneto motive force produces its quantum of flux just like the equivalent magnetic shell given by $mL \equiv iL^2$, and that all magnetic phenomena without exception may be regarded as the vector sum of all the magnetic shells due to all externally applied magneto motive forces, together with those due to internal magneto-motive forces arising from the polarisation of the electronic orbits in iron or other magnetic material.

The consequence of this interpretation is that the only permeability is that of vacuum, and it has no dimensions because of the equivalence In dealing with circuits containing iron, however, it is immaterial whether the increased flux be ascribed numerically to increased magneto-motive forces or to increased permeability, hence the variable μ may be retained but always as a numeric.

We can deduce from the fact that $\mu_0 = 1$, that $c^2 = 1/K_0$ and also that the electrostatic system of dimensions disappears, but let us develop this result more slowly

A consequence of all magnetic phenomena being electromagnetic is that equation (2) becomes a particular integral of equation (4), whence $mm'/\mu_0 = ii'L^2/A'$, and if $m \equiv iL$, $A' = \mu_0 = 1$ From equations (1) to (4), $e^2/K_0 = m^2/\mu_0 = e^2V^2/A'$, and if $A' = \mu_0 = 1$, then $e^2/m^2 = K_0 = 1/V^2$ The velocity of electromagnetic waves derived from equations (1) to (4) is given by $c^2 = A'/\mu_0K_0 = 1/K_0$ which agrees with Maxwell's electromagnetic system, since μ_0 is a numeric in that system

The result of the simple assumption that all magnetic phenomena are in fact electromagnetic and that Faraday's equivalence between an electric circuit and a magnetic shell is a real equivalence, in the sense of being synonymous, or different aspects of the same phenomena, is that electrical science is reduced to a singular system of dimensional quantities agreeing with Maxwell's electromagnetic system, and the electrostatic system disappears The numerical values of the units of course remain unaltered

Humidity in Relation to Sheep Blowfly Attack

IN a recent letter to NATURE[1], Holdaway and Mulhearn conclude that (in Australia) "there is a relation between sweat content and susceptibility to weather stain and body strike" by blowflies It is not clear whether they regard the predisposing factor to be the accumulation of sweat constituents (suint) in the wool (from the reference to yolk colour such would be presumed) or the excessive moisture produced by sweating

In studies on the blowfly problem in Great Britain, it seemed desirable at the outset to investigate the rôle of humidity in relation to sheep maggot attack. *In vitro* experiments showed that eggs and first instar larvæ of *Lucilia sericata*, Meig, are highly susceptible to dry conditions and would not be able to survive on the sheep's skin unless the humidity exceeds 90 per cent for several hours The humidity of the fleece, therefore, is a vital factor in sheep maggot attack. A technique was devised for measuring the humidity of the microclimate at the base of the wool and observations were made under various meteorological conditions on Welsh sheep, a breed susceptible to blowfly attack It was found that the humidity at the wool base was surprisingly low over the back, ranging from 38 to 78 per cent but seldom exceeding 70 per cent even in showery conditions However, in the region of the breech, the humidity was often high owing to the soiling of the wool with fæces or urine; this is the site of the majority of attacks in this country. It can be concluded that normally the humidity at the base of the wool is too low for the development of larvæ of *Lucilia sericata*. This was confirmed by placing eggs and young larvæ on sheep, when myiasis did not result unless the wool was kept wet by frequent watering. Also, we have on several occasions found desiccated eggs and larvæ on sheep in the field.

In Australia among Merinos, body strike is

associated with an infectious condition of the wool producing "weather stain" and it is prevalent following "excessive rains and humid conditions generally" Attacks on the back are not uncommon in this country, in fact, they were especially prevalent in North Wales during the *dry* summers of 1933 and 1934, infestation usually beginning in the region between the shoulder-blades Clearly, the humidity at this spot must sometimes become abnormally high, perhaps owing to excessive sweating The humidity at the wool base was occasionally found to be higher in this region than elsewhere on the back

We have, therefore, concluded that in Great Britain, whether fæces, urine or sweat be responsible, it is the moisture in each instance which permits the establishment of sheep maggots

These results will shortly be published in detail elsewhere

Mutations and the Ageing of Seeds

M Navashin[1] and his co-workers reported in a series of papers that plants produced from old seeds in *Crepis* show a great percentage of 'mutations' Similar observations were reported by Cartledge and Blakeslee[2] and by Peto[3] in America working with various plants They confirmed the results found by Navashin and his co-workers All these authors state that Navashin made this discovery. Hugo de Vries, however, in his "Mutationstheorie" (1901)[4], reported that in one case five-year old seeds from *Oenothera* gave 40 per cent instead of 5 per cent mutations (p 185) He interpreted this phenomenon by postulating a longer viability of the 'mutated' seeds (p 186)

More extensive studies on the ageing of the seeds in *Oenothera* were reported by Nils Heribert Nilsson (1931)[5] He summarised his observations in a table and from the results obtained he drew the following conclusion "Mit dem Alter des Samens, also mit der herabgesetzten Keimfähigkeit, geht das Ansteigen des Mutationsprozent ausgesprochen parallel" (p 326).

Recent investigations (see, Cleland, Darlington, Gates, Renner, Oehlkers, and others) showed that some of the mutations in *Oenothera* are due to segmental interchanges between non-homologous parts of the chromosomes Consequently the mutations reported by H. de Vries and N. Heribert Nilsson are obviously due to chromosomal alterations Chromosomal alterations (but not gene mutations) were reported by Navashin too, that is, Navashin confirmed cytologically the observations reported by de Vries and Heribert Nilsson

Vitamin B_1 and Blue Fluorescent Compounds

Fluorescence in ultra-violet light (screened by Wood's glass) is not a property of vitamin B_1; but I have found that the purest preparations in our possession (method of Kinnersley, O'Brien and Peters, 1933[1]) can be converted by oxidation in aqueous solution into substances showing an intense sky-blue fluorescence

Blue fluorescent compounds are stated to arise as breakdown products of the yellow fluorescent flavins (Kuhn, *et al*[2]), hence the Bence Jones 'quinoidine' substances in yeast extracts (Kinnersley, Peters and Squires[3]) can originate from vitamin B_1 as well as from vitamin B_2 Arising from my observation upon vitamin B_1, it seems to be possible for the first time to postulate a relation between vitamin B_1 and the pyrimidazine group In this connexion it is interesting to note that the empirical composition $C_{12}H_{16}ON_4S$ of vitamin B_1 (Windaus *et al*[4], Holiday *et al*[5]) corresponds with that of a thio-hexahydro lumichrome (lumichrome $C_{12}H_{10}O_2N_4$) The hydrogenation of the azine or benzene rings may account for the strength of the vitamin as a base and for its high water solubility

The several lines of investigation thus indicated are being actively pursued by ourselves and colleagues, though it is admittedly difficult to reconcile our working hypothesis with the formation of the particular degradation products of vitamin B_1 recently described by Windaus, Tschesche and Grewe[6] So far, it has not been found possible to replace vitamin B_1 with flavin in the specific respiration of avitaminous brain tissue, which is catalysed by vitamin B_1[7]

Testing for Unconsciousness After an Electric Shock

It has been definitely proved that the tests of consciousness used in chloroform anæsthesia cannot safely be assumed to be valid in the case of an animal or person who has been immobilised as a result of an electric stimulation of the brain The matter is of great importance because, as a result of the Slaughter of Animals Act, electric immobilisation is being extensively used in the slaughter-house as an alleged anæsthetic, and its use for operations, both veterinary and experimental, has been proposed

The object of this letter is to point out that there exists a strong tendency to stifle inquiry into this unsettled question, and to discourage further investigation by making statements which imply that electrolethalling has been proved to cause genuine anæsthesia It is not difficult to explain this tendency to brush aside unsettled questions, for there are strong motives for desiring to believe that electrolethalling, as practised in the slaughter-house, is humane Moreover, vested interests have grown up around the practice, and humanitarians who have

prematurely endorsed it are reluctant to believe that their judgment may have been wrong

Many wild theories have been put forward with the object of explaining the observed phenomena in accordance with the wishes of those who propound them, and objective data on the subject are extremely restricted in their scope The following facts appear, however, to be established —

(1) It is possible to produce, by passing a suitable electric current through the brain, a nightmare state in which the subject retains his senses, but appears to an external observer to be completely unconscious, the pupil reflex being absent The conditions under which this state can be produced have not been satisfactorily delimited, but they appear to approach those employed in the slaughter-house The requisite range of conditions, whatever it may be, is one which sometimes although very rarely occurs in electrical accidents

(2) A weak interrupted direct current produces the same objective phenomena as sinusoidal (electrolethaller) current twenty times stronger as read with an ammeter. Thus it is found that to get the desired objective effects on pigs in the slaughter-house the sinusoidal electrolethaller current must lie roughly between half an ampere and one ampere, while Regensburger gets similar results with 10-per-cent-interrupted direct current of from 31 to 53 milliamperes

(3) Controlled experiments on human beings have not been carried quite up to the point where the subject fails to recover his mobility immediately on the cessation of the current In slaughter-house practice the current strength lies just above this point, and it must have done so in the case of those rare electrical accidents in which the nightmare state persisted after the accident.

(4) Leduc submitted himself to interrupted direct current up to 4 milliamperes but failed to reach unconsciousness, although his assistants supposed him to be completely unconscious for twenty minutes He felt sure, however, that if the current had been raised a very little higher unconsciousness would have ensued Dr J Hertz, in Paris, therefore repeated the experiment on incurable invalids with currents up to 25 milliamperes (or 18 milliamperes where the on period was 10 per cent) but Leduc's prediction was not fulfilled The subjects failed to pass beyond the nightmare state They exhibited permanent dilation of pupils and were unable to respond to stimuli, but they retained their sensibility.

(5) Breathing was sometimes inhibited during the nightmare state in Hertz's subjects, and in some victims of electrical accidents. Zimmern in particular refers to an accident in which the victim knew that he could not breathe voluntarily and dreaded that artificial respiration might be abandoned prematurely

(6) The muscles in Hertz's subjects were sometimes contracted and sometimes relaxed The absence of squealing in electrolethalled pigs is not therefore necessarily due either to muscular contraction or to unconsciousness It may, for all we know, be due simply to the nightmare state.

(7) Whether the pigs, if conscious, suffer pain from the current must depend on whether their muscles are relaxed or violently contracted Both conditions may occur in practice.

I intend to publish before long a more detailed statement of the above points, the purpose of the present letter is to urge that every effort should be made to encourage inquiry into an unsettled question, with regard to which we require new data based on research and not dogmatic assertions based on the will to believe.

C W. Hume.

Magnetism of Tin

S Ramachandra Rao has reported[1] that, on testing colloidal powders of white tin magnetically, its paramagnetic susceptibility becomes diamagnetic as the particle size decreases, this diamagnetism increasing as the particle size decreases. A few years ago we often observed the same phenomenon in the investigation of the effect of cold-working on the susceptibility of white tin. In our case we found that the paramagnetic susceptibility of white tin changes its sign as the internal stress caused by cold-working increases, this value of diamagnetism increasing in proportion to internal stress This change of susceptibility has been explained by a slight expansion of tin by cold-working[2].

Thus the interesting phenomenon observed by S R Rao may be explained as follows As a theoretical calculation shows, the lattice constant of a metal is somewhat larger in the surface layer than in the interior, the constant attaining gradually its normal value at some hundred layers below the surface Hence it is to be expected that, as the particle size of tin diminishes, its mean lattice constant increases; the result of colloidalisation is therefore the same as that of cold-working Hence we may assume that through the volume expansion due to colloidalisation of tin, its magnetic susceptibility is affected in two different ways:

(1) The decrease of paramagnetic susceptibility due to the diminution of free electrons caused by the expansion.

(2) The increase of diamagnetic susceptibility due to the increase of bound electrons caused by the expansion

In the case of cold-working of white tin, its susceptibility is observed to change, for example, from $0\ 027 \times 10^{-6}$ to $-0{\cdot}0049 \times 10^{-6}$, corresponding to a change of density by cold-working from 7·291 to 7 280 The calculated value of the susceptibility corresponding to this change of density is from $0{\cdot}0270 \times 10^{-6}$ to $-0{\cdot}0051 \times 10^{-6}$; the agreement between the observed and theoretical values is satisfactory. It may, therefore, be concluded that the curious change of susceptibility from a positive to a negative value in the case of colloidalisation is due to the increase of the mean lattice constant due to refining of tin particles; but a quantitative comparison between the theoretical and observed values cannot be made, as the change of density caused by colloidalisation has not yet been measured.

Magnetic Induction in a Supra-Conducting Lead Crystal

In our last note[1] we showed the relation between magnetic induction and field strength in the case of a polycrystalline lead rod. We now report shortly on analogous experiments carried out with a lead single crystal.

The measurements were carried out at various temperatures with the second method that we described, the magnetic moment of the supra-conductor being determined in a constant field. One may conclude from Fig. 1, in which the results of our measurements at 4.24° K. are shown (full curve), that the destruction of supra-conductivity occurs in almost the same way in single crystals and in polycrystalline lead. The sudden rise of the induction begins almost exactly at the same critical field strength H_k as in polycrystalline material; however, in single crystals the transition region, that is, the field interval in which the transition from one state to the other begins and terminates, is considerably narrower, extending over merely 7 gauss. In the transition region, the induction is observed to rise slightly with time in a constant magnetic field.

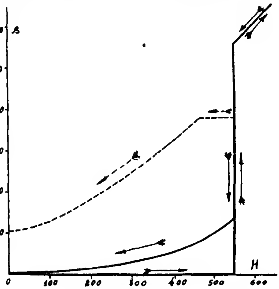

Fig. 1.

However, the reverse process, the appearance of supra-conductivity on moving from strong fields to fields less than H_k, is found to be different for single crystals and polycrystalline rods. For comparison, the dotted curve on the same figure shows the relation between B and H for polycrystalline lead. It appeared that in this transition the induction followed a change in the field strength slowly, the process depending strongly on time. The dependence on time was particularly strong in the transition region of the field strength—the same field strengths as those at which the supra-conductivity was destroyed—where even after waiting for half an hour we did not succeed in reaching a state of equilibrium, the induction still changing with noticeable velocity. As the period of our experiments was limited by the speed with which the helium evaporated, the curves which we obtained in decreasing magnetic fields do not correspond to the equilibrium state. On decreasing the field strength to zero a residual magnetisation is observed, which in different experiments varied between 0 and 2 per cent of the maximum of B in the transition region. It was found that the residual magnetisation sank noticeably with time.

The strong dependence on time and the small hysteresis in single crystals have convinced us that all states of a supra-conductor with an induction differing from zero are unstable. These experiments again confirm the concept of two phases, an ordinary and a supra-conducting phase with an induction equal to zero. The transition from the supra-conducting to the ordinary phase occurs rapidly, whereas the reverse transition takes place more slowly. It is interesting to note that the latter process occurs so gradually that a fairly sensitive telephone in connexion with an amplifier is insufficient to detect any spontaneous changes in the induction.

Symbols for Chromosome Numbers

While in entire agreement with Prof. Gates's view[1] that a convention should be agreed upon to distinguish between the basic and the haploid chromosome number, I am not convinced that the introduction of a new symbol is necessary. The use of x to indicate the basic number, leaving n for the haploid number, has been the standard practice in this laboratory for the last three years[2]. In spite of Prof. Gates's fears, no confusion seems to arise from its use. I may also point out that a Greek letter has the grave practical disadvantage of being troublesome to print and impossible to type on an ordinary machine.

Publication of *Nomina Nuda*

We wish to support the appeal of Sir Sidney Harmer in Nature of December 22 (p. 973) for the suppression of *nomina nuda* by editors of scientific publications.

Editors, however, cannot always be expected to recognise the character of names which, like the one that has caused Sir Sidney Harmer's protest, may perhaps be called *nomina seminuda*. We would further appeal, therefore, to writers of zoological papers to avoid using names that are not formally introduced according to the rules of zoological nomenclature.

Points from Foregoing Letters

X-Ray investigation of thin films of myosin, the protein substance of the muscle, by Mr. W. T. Astbury and Mrs. Sylvia Dickinson, shows that this substance, when stretched, behaves very much like α-keratin, which is derived from hair. Keratin differs from myosin mainly in containing the sulphur compound, cystine; the authors raise the question whether hair might not be considered as 'vulcanised' muscle.

Prof. G. Hevesy points out that, while the isotopes of potassium of atomic weight 40 or 41 may be responsible for its radioactivity, there still remains the difficulty of reconciling the computed long life of these isotopes with the half-million volt energy of the electrons emitted by potassium. Prof. F. H. Newman and Mr. H. J. Walke suggest that the radioactivity of potassium may be due to extremely small amounts of an isotope of weight 40 hitherto undetected, which may have arisen from the action of neutrons upon the abundant calcium isotope of the same atomic weight.

Copper and lead, though of greatly different atomic number (29 and 82), are found by Dr. Giulia Alocco to absorb the more penetrating cosmic particles to the same extent. The softer cosmic shower producing 'radiation' is unequally absorbed by substances of different atomic number.

Certain irregular variations with time in the amounts of cosmic rays are found by Prof. V. F. Hess and Dr. W. Illing to be due mainly to the softer components and to be related to variations, in the opposite sense, in the horizontal component of the earth's magnetic field.

Dr. Leo Szilard and Mr. T. A. Chalmers report that the heavy element indium, when bombarded with neutrons, yields radioactive substances of three different life periods. Since indium has only two known isotopes (113 and 115), one of them must be activated with two periods. This had been observed previously only with light elements.

The radioactivation of iodine by means of neutrons liberated from heavy water by the gamma rays of radium is reported by Dr. T. E. Banks, Mr. T. A. Chalmers and Prof. F. L. Hopwood. This raises interesting questions concerning atomic transmutations that might be brought about within the living body.

The ordinary hydrogen molecule (H_2) is the simplest known molecule, and the first task of any physical theory that aims at explaining the nature of matter is to account for its structure, as indicated by its spectrum. Prof. O. W. Richardson reports several new systems of bands in the H_2 spectrum, and discusses the electronic configuration that might account for them.

Europium bichloride gives in ultra-violet light a brilliant purplish-pink fluorescence, the spectrum of which contains a broad band in the blue, identical with that given by fluorite under the same condition. This is considered by Dr. K. Przibram as additional evidence that the blue fluorescence of fluorspar in ultra-violet light is due to the presence in that mineral of the rare element europium, in the form of a bivalent salt.

In the spectrum of the light scattered by liquids (Raman effect) two 'wings' of continuous light usually appear at the sides of the primary line. Dr. E. Gross and Mr. M. Vuks bring evidence from the light scattering behaviour of diphenyl ether to show that these 'wings' are not due to the rotation of the molecules, as usually assumed, but to the vibrational Raman effect.

Synthetically produced auxin, the hormone responsible for growth by the elongation of the cells, is found by Dr. K. V. Thimann and Mr. J. B. Koepfli to be also fully active in promoting root-formation on pea cuttings. From this they deduce that the growth promoting and root-forming substances of plants are identical.

From the rate at which eyes are regenerated in decapitated (well fed but previously starved) flatworms (*Dendrocoelum*), Dr. A. A. Wolsky deduces that starvation reduces the amount of formative material available for regeneration.

Cosmic dust coming from inter-planetary space is probably responsible for the luminous night clouds observed in Norway and Canada. Prof. Carl Störmer gives particulars of their height (82 km.) and velocity, as determined in Norway during 1933 and 1934; he suggests that the clouds are chiefly illuminated by ultra-violet rays.

The 'swishes' or 'whistlers' sometimes heard in radio receivers are produced, according to Mr. T. L. Eckersley, by the dispersion of a sudden pulse travelling through the electrically-conducting layer of the upper atmosphere (ionosphere) and reflected at the polar regions. Mr. Eckersley brings evidence to prove that the observed change in frequency with time in the case of a 'swish pair' agrees with that to be expected from his theory.

The usual method of separation of heavy from ordinary water depends upon the fact that, during electrolysis, ordinary water is decomposed first, leaving the heavy component behind. Dr. F. P. Bowden and Mr. H. F. Kenyon have measured the over-potential of heavy hydrogen as compared with the ordinary variety and from its value calculate that, under optimum conditions of electrolysis, about fourteen times more H_2 than D_2 is liberated at the cathode.

Sir James Henderson proposes to simplify the dimensions of electrical and magnetic quantities, basing his suggestions on the view that all magnetic phenomena are due to electronic motion. He postulates that the only permeability is that of vacuum and that it has no dimensions. This makes $\mu_0 = 1$ and $K_0 = 1/c^2$, so that the electrostatic system of dimensions disappears.

A sky-blue fluorescence in ultra-violet light is developed, upon oxidation, in the anti-beriberi vitamin (B_1). Prof. R. A. Peters reports this change and indicates its bearings on the, as yet undetermined, chemical constitution of vitamin B_1.

The change in the magnetic susceptibility of white tin from para- to diamagnetic when it is reduced to a colloidal powder, as observed by Dr. S. R. Rao, is analagous to the same magnetic change produced by cold working, according to Prof. K. Honda and Dr. Y. Shimizu. These authors explain both phenomena as due to the different atomic arrangement in the surface layers from that in the interior, the lattice constant being larger in the surface layer.

Sir John Flett, director of H M Geological Survey, for his researches "concerning the mineral structure of the Earth" in the realms of petrological, palæontological and stratigraphical geology, Murchison Medal to Prof E B. Bailey, professor of geology in the University of Glasgow, for his researches in stratigraphical and tectonic geology; Lyell Medal to Prof D M S. Watson, Jodrell professor of zoology and comparative anatomy in University College, London, in recognition that he has "deserved well of the Science" in the fields of palæontological and stratigraphical geology, Bigsby Medal to Prof H H Read, George Herdman professor of geology in the University of Liverpool, "as an acknowledgement of eminent services" to petrological, structural and stratigraphical geology The balance of the Wollaston Fund has been awarded to Dr. W J Arkell, of the Murchison Fund to Mr J V Harrison, and of the Lyell Fund to Mr J J Hartley and Mr L R Wager

Edison Medal Award

THE Edison Medal for 1934 has been awarded by the American Institute of Electrical Engineers to Prof Willis R Whitney, "for his contributions to electrical science, his pioneer inventions, and his inspiring leadership in research" The Edison Medal was founded by associates and friends of Thomas A Edison, and is awarded annually for "meritorious achievement in electrical science, electrical engineering, or the electrical arts" by the American Institute of Electrical Engineers Prof Whitney has been vice-president in general charge of research of the General Electric Company, Schenectady, New York, since 1932

Equivalence of Energy and Inertial Mass

ON December 28, during the meeting at Pittsburgh of the American Association for the Advancement of Science, Prof. A. Einstein delivered the Josiah Willard Gibbs Lecture of the American Mathematical Society. The accompanying summary was provided by Prof Einstein for the use of Science Service: "It is well known that the equivalence between energy and inertial mass is one of the most important consequences of the special theory of relativity, this principle forms at present a useful tool of research in the physics of atomic nuclei. The theoretical derivation of this principle of equivalence, while restricting myself to what is conceptually necessary, is the subject of my lecture. From the Lorentz transformation and the assumption of the impulse and energy principle for material particles, the form of the impulse and energy of the moving particles, as well as the equality of mass and rest-energy, is derived. The whole proof is based on the consideration of an elastic and an inelastic collision between two identically constituted material particles."

Limits of Industrial Employment

DR. E. C SNOW, in a paper read before the Royal Statistical Society on January 15, discussed "The Limits of Industrial Employment—the Influence of Growth of Population on the Development of Industry". The first part of the paper dealt in considerable detail with the facts of growth of population in the nineteenth century and up to the outbreak of War During a considerable part of that period, the population of England and Wales was increasing at the rate of 300,000–350,000 per annum—entirely due to the decline in the death rate This decline in mortality was not peculiar to industrialised Great Britain, but was equally marked in other agricultural countries The analysis of the statistical evidence seems to justify the view that the growth of industry in Great Britain was not the direct cause of the increase in population The population circumstances of England and Wales at the present time are widely different from those ruling up to the time of the War The population at ages under thirty-five years is declining At ages over sixty it is still increasing, but the net effect is an annual increase of population of not more than a quarter of that before the War The economic effect of the smaller rate of population growth now is indicated by the fact that the quantity of foodstuffs imported since 1924 has increased at less than 1 per cent per annum The overseas countries which rely on this market for an outlet for a large part of their production of foodstuffs are living in the expectation that Great Britain can increase its imports of food at the old rate of 5 per cent per annum, whereas, in fact, it has for some time only been increasing at the rate of 1 per cent per annum, and before long even this small rate of increase is likely to decline

Russian Academy of Sciences

THE recent decision of the Soviet Government to transfer the Russian Academy of Sciences and its affiliated institutions from Leningrad to Moscow marks the beginning of a new period in the history of the Academy, which dates back more than two hundred years As is pointed out in the *Izvestia*, the transference is not a measure dictated merely by consideration of convenience Indeed, the accommodation which has to be provided at short notice for more than a hundred institutes, laboratories, museums, etc, forming the Academy is only obtainable in the already overcrowded Moscow mainly at the expense of other institutions, which are being moved elsewhere New and spacious buildings are being erected at a 'shock speed', but mostly just planned, while many of the institutions are actually moving. In addition, living quarters have to be provided for the thousands of academic officials and their families, since all flats, rooms, etc in Moscow are under the strictest State control. All these difficulties have resulted from the recent decree by which the Academy has been brought under the direct control of the Soviet of the People's Commissars Now statutes for the Academy are being prepared in order to replace "the old traditions of purely academic outlook" by work on problems connected with the "socialistic reconstruction" of the country. While the new order will possibly mean increased material support for some of the academic institutions, the decision as to whether or not a certain branch of abstract research deserves support will apparently be now in the hands of laymen officials.

Association of British Zoologists

THE annual meeting of the Association of British Zoologists was held on January 5, in the rooms of the Zoological Society in Regent's Park, under the presidency of Prof F. Balfour Browne The morning session was given to a discussion of the general trends of zoological science at the present time In opening the discussion, Prof D M S Watson defined zoology as the science of animal life in all its aspects He emphasised the recent tendency of zoology to return from the strictly taxonomic and morphological outlook of the latter part of the last century to the more biological outlook of pre-Darwinian zoologists He concluded that the reason for this tendency, in spite of the undeniable importance of a knowledge of comparative morphology for all branches of zoology, is that the time is now past when important alterations in our conceptions of morphology are likely to occur He thinks that the greatest need to-day is a wider knowledge of the animal as a living thing, and of those branches of zoology, such as comparative physiology, embryology and genetics, on which knowledge of animal life must rest In recent years this need has been brought even more clearly to the front by the great extension of the economic applications of zoology

IN the discussion which followed, there was almost complete agreement with Prof. Watson both in his definition of zoology, and in the emphasis which he laid on the development of zoology as the study of the living animal Dr. J Gray dwelt on the need for teachers to treat the animal as a living thing. In the past, and still to a large extent to-day, zoological teaching has, he thinks, failed to give a broad picture of animal life · to repair this failure is its most pressing need In comparative physiology, which provides a large proportion of the essential knowledge for the science of animal life, the aims of the zoologist are similar to those of the medical physiologist, and he must follow similar methods Dr E S Russell agreed with earlier speakers in regarding zoology as the science of animal life, and stressed the necessity in such a science of returning to the earlier conception of the animal as an organism and discarding the analytical outlook which originated with the development of the cell theory Prof. E W MacBride also accepted the study of animal life as a definition of the aim of zoology He emphasised the importance of habit in the life and evolution of animals and therefore in zoological science. In the afternoon, several members of the association demonstrated applications of photographic methods to biological research Mr F. S J Hollick described an apparatus for recording the movements of insect wings in flight and the air currents set up by their movements, while Mr. A. G Lowndes gave an account of his most recent methods of photographing the movements of small animals by means of an instrument in which the stroboscope and cinematograph are combined

Cancer Research

AT the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on January 14, the following additional grants for 1935 were approved —£200 to Dr Ralston Paterson for the part-time services of a radiologist at the Holt Radium Institute, Manchester; £250 to the Strangeways Research Laboratory, Cambridge, for the services of Dr A Glucksmann, £200 to Dr Edith Paterson, at Manchester and £1,000 to the Radium Beam Therapy Research for the salary of qualified research workers The Scientific Advisory Committee has been allotted a sum of £500 for the year 1935 for the salary and expenses of a research worker to carry out, under its supervision, an investigation of the action of radiation on colloids. The National Cancer Association of South Africa, which is representative of the research organisations of the Cape, Transvaal, Natal and Orange Free State, has been approved as a body affiliated to the British Empire Cancer Campaign The Ottawa correspondent of *The Times* states that Canada will commemorate the twenty-fifth anniversary of the accession of King George to the throne by establishing a national fund for a campaign against cancer in Canada

Decreasing the Number of Motor Accidents due to Skidding

CONCLUSIONS on this topic arrived at by Prof. R. A Moyer, of Iowa State College, as set out in a paper read to the Highway Research Board, have been reported by Science Service, Washington, D C An exhaustive study of the skidding characteristics of motor-car tyres on various types of road surface indicates that the most important anti-skidding factor on the highway is to cover its surface with gritty particles so that it acts like sandpaper The marked increase in the speed of vehicles on highways has led to a serious problem. The coefficients of friction between road surfaces and rubber tyres become smaller as the speed increases, and so skidding becomes easier. All stopping distances and centrifugal forces on curves increase as the square of the speed; that is, if the speed is doubled the shortest possible distance for stopping is increased four times and the necessary road friction is also increased four times Highway engineers have been considering the possibility of building curves in spiral transmission fashion when the speed exceeds fifty miles an hour. In fast driving, in order to negotiate curves, the driver finds it easier to move from one side of the road to the other, but on blind curves this is a danger to approaching cars. Engineers are considering the possibility of building curved roads of such a shape that this tendency of drivers of fast cars may cease to be a menace to cars coming in the opposite direction. Prof. Moyer also points out that the application of the brakes when the car is going round a curve increases the tendency to skidding sideways but that the application of power decreases this tendency For uniform braking the distribution of the load should be such that more weight falls on the back wheels than on the front wheels.

Position of the American Negro

RACIAL unity, racial pride and racial traditions have been of late subjects of discussions in which

passion and prejudice have been more conspicuous than exact knowledge From Vanderbilt University, Nashville, Tennessee, one of the smaller privately controlled universities of the United States, we have received a volume of abstracts of theses presented during 1933–34 by candidates for advanced degrees and, among them, a study by a candidate for the doctorate of philosophy of a movement for fostering these elements of culture among a 'non-Aryan' group, namely, the American Negro It seems that since towards the close of the nineteenth century a sustained effort to develop race-conscious feeling so as to achieve "the internal unity and sentimental solidarity necessary to give the race a life more or less separate from other groups" has accompanied a vigorous struggle for recognition and status Especially in the five years 1910-15, the aims and purposes of the movement became definitely established, a recognised leader emerged and formal machinery for its further promotion was created At the present time, extensive provision is made by Negro colleges and universities for courses of instruction in Negro life and history, and numerous activities have developed outside the class room designed to make students better acquainted with Negro tradition pageants depicting Negro progress and achievement, essay competitions, the celebration of Negro History Week, exhibitions of Negro art and literature and music festivals featuring Negro folk music. By making his history and tradition extensively known outside the community, it is assumed that the Negro will gain a larger measure of recognition and respect from the world at large for his worth and capacity.

History and Uses of Paraffin Wax

IN his paper read before the Institution of Petroleum Technologists on December 11, 1934, on the "Utilization of Paraffin Wax and Petroleum Ceresin", Mr. P G. Higgs outlined the history of petroleum wax from its discovery in 1830 to its production on a commercial scale Its use for a long time was restricted, since combustibility alone of all its useful properties was universally acknowledged as of market value Time has shown, however, that paraffin wax can be used in cases where its characteristics of resistance to water, inertness, good electrical properties, etc., are invaluable. Thus to-day, apart from its chief function as an illuminant, it is employed, for example, as a proofing agent for porous materials, in the manufacture of waxed paper and paper boards, as an external coating to wooden receptacles for the preservation of foodstuffs, as an ingredient of polishes and in the electrical industry for insulating purposes. In addition, it is used in the form of an aqueous emulsion in the sizing of paper, as a size in the weaving of cotton, and as a glossing agent in the laundry trade

PETROLEUM ceresins, the most recent addition to the range of paraffin waxes, are characterised by a relatively high setting point and micro-crystalline structure. Experiments have shown that the addition of 0·3 per cent or less to commercial paraffin wax alters the structure of the whole practically to micro-crystallinity. Moreover, in the case of candles made from paraffin wax to which a similar small percentage of ceresin has been added, resistance to bending is substantially increased Initially, the strong colour of petroleum ceresin was a disadvantage in this connexion, but this is overcome by incorporation of the ceresin during the manufacture of the paraffin wax and refining the two together The resultant product, while having a pleasing colour, also lacks, or has in a much lesser degree, the defects usually consequent on marked crystallinity of the paraffin wax It is reasonable to suppose, therefore, that the usefulness of paraffin wax could be still further extended by the addition of small quantities of petroleum ceresin Whether it is better to manufacture 'doped' waxes or leave the 'doping' process to the user is, however, still an open question

Water Purification by Ozone

IN *Engineering* of January 4, Mr T Rich gives an account of the development of the treatment of water by ozone which has resulted from the researches made by P Otto in 1898 in connexion with his thesis for a doctor's degree at the Sorbonne. When Dr. Otto was carrying out his experiments, the question of potable water supplies in France was becoming a matter of concern, and, encouraged by Pasteur, he took up the design of ozone water sterilisation apparatus for outputs varying from that through a single tap to that required for large cities. One of the first important installations laid down to his designs was that for Nice, and since this was constructed many other places on the Riviera have followed the example of Nice, owing to serious outbreaks of typhoid. In 1932, the scientific commission for the study and control of the water supply of Paris decided to supersede the use of chlorine by the use of ozone for treating water taken from the Seine and the Marne, while quite recently an important ozone-sterilisation plant has been put into commission for the water supply of Nancy, a manufacturing city of 120,000 inhabitants. There are other plants in operation in Belgium, Italy, Rumania and on the Congo, and the system has been applied to the water supply of large passenger vessels. The principal apparatus in a plant is the electrically-worked Otto ozone generator, and of this Mr. Rich gives a full description

Grey and Red Squirrels in England

IN the report on animal numbers, issued by the Oxford University Bureau of Animal Population at the end of 1934, the director, Mr A D. Middleton, states that the evidence from the Bureau's three hundred or so observers in various parts of Great Britain points to another serious increase of the American or Carolina grey squirrel (*Sciurus carolinensis*, Gmelin) and also an increase of the native British red squirrel (*Sciurus leucorous*, Kerr) after the setback due to disease outbreaks of a species of *Eimeria* (Coccidia) noted in 1931. During the last three years, the report points out, the British red squirrel seems to have been steadily regaining

its former status in most parts of the country and is now commonly seen in many districts where the American grey squirrel is not present Even within the area occupied by the grey squirrel, red squirrels have frequently been seen during the past two years The American grey squirrel, after its severe set-back in 1931, due mainly to disease, was in comparatively low numbers during 1932 and 1933, but there are now many indications that a period of increase is well on the way It has gradually extended its range, spreading outwards from the main areas previously occupied (home counties, Midlands, Central Yorkshire, Cheshire, North Wales, Dunbartonshire, Fife and the environs of Bournemouth, Exeter and Edinburgh); several have been found in an isolated wood near Woodbridge, in Suffolk "Should the numbers increase greatly over this large area," adds Mr Middleton, "it seems probable that the grey squirrel may become of more serious economic importance than hitherto" The Oxford University Bureau is now extending its national investigations of animal numbers to the Japanese deer (*Cervus sika*) which have escaped from many English parks and taken to living wild in the woods of the home counties and the south, and of harvest-bugs (*Trombidiidae*)

Scientific Correspondence of Sir James Smith (1759–1828)

The main portion of Part 1 of the Catalogue of Manuscripts in the Library of the Linnean Society of London is devoted to the scientific correspondence of the first president of the Linnean Society, and Mr. Warren Dawson has abstracted the more important matters referred to in more than 3,000 letters received by Sir James Edward Smith (1759–1828) (Catalogue of the Manuscripts in the Library of the Linnean Society of London, Part 1 The Smith Papers The Correspondence and Miscellaneous Papers of Sir James Edward Smith, M.D, F R S, First President of the Society By Warren R Dawson, F R S E Pp 114. London The Linnean Society, 1934 10s net) It is a careful piece of work, the completion of which confers a benefit on all who are interested in the natural history of the period immediately following Linnæus's death, and the transference of his collections to England six years later The correspondents include many distinguished naturalists both at home and abroad, and some of their letters are valuable documents from the point of view of the history of biology Sir James Edward Smith was primarily a botanist, but as possessor of Linnæus's collections for about forty-five years he had wide interests as a naturalist He was one of the founders of the Linnean Society of London, his co-founders being the Rev. Samuel Goodenough, afterwards Bishop of Carlisle, and Thomas Marsham, an entomologist

International Aspects of Drug Addiction

In the Norman Kerr Memorial Lecture on this subject published in the January issue of the *British Journal of Inebriety*, Sir Malcolm Delevingne, late Deputy Permanent Under-Secretary of State and British representative on the Opium Advisory Committee of the League of Nations, showed that the international treatment of the problem during the last fourteen years has afforded a striking example of what can be accomplished in a difficult field by international co-operation, aided by the machinery of the League of Nations. After a historical sketch of the subject with special reference to the conferences at the Hague and Geneva, he dealt with the present position, showing that a system of control over the export and import trade is in operation, which if universally and effectively adopted is practically watertight The illicit traffic however still continues to flourish, owing to a resort having been made to clandestine sources of supply or to parts of the world where control is less strict or non-existent In dealing in conclusion with the medical and scientific aspects of the problem, Sir Malcolm briefly alluded to the treatment and after care of the addict, the possibility of replacing the drugs wholly or partly by less dangerous substances, the rate of consumption of the drugs in different countries, and the question as to whether new drugs are habit-forming or not

Engineering Research in Japan

In vols. 10 and 11 of the *Japanese Journal of Engineering* recently issued by the National Research Council of Japan (Imperial Academy House, Veno Park, Tokyo), abstracts of varying length are given of some 400 papers on civil engineering, naval architecture, technology of ordnance, electrical engineering, mine engineering and metallurgy The abstracts are printed in English, and about three-quarters of them relate to various aspects of electrical engineering. Some of the papers have been contributed to the Institution of Electrical Engineers of Japan, while others contain reports of researches carried out at the Electrotechnical Laboratory, Ministry of Communications, Tokyo, and at research institutions and universities Corresponding journals issued by the National Research Council contain abstracts of papers on astronomy, chemistry, physics, botany, zoology and other branches of science

Contour Maps of the East

Among the latest additions to Bartholomew's General World Series are maps of the Middle East (Persia, Iraq, Palestine, Syria, Turkey and North Arabia) and the Far East (China, Japan, Korea and Manchukuo) on scales respectively of 1 . 4,000,000 and 1 : 6,000,000 The maps are contoured and layer-coloured in green, brown and purple. Political and provincial boundaries are clearly marked, and on the map of the Middle East the chief roads, routes and caravan tracks are shown, as well as airports All railways and the principal steamer routes are given. The scale allows a considerable amount of detail and a large number of names. The printing is clear, and the maps should prove most useful. The price of each map mounted on cloth and folded is six shillings

The *Cape Naturalist*

IN November there appeared the first number of the *Cape Naturalist*, which is designed to increase the interest of non-technical readers in Nature and archæology in South Africa A striking cover reproduces the flower of *Stapelia*, the colour and carrion like odour of which attracts blowflies which pollinate the flowers, and sometimes, deceived by the smell, deposit their eggs upon the petals The articles are short and varied enough to make a general appeal (Pp 24, price 7*d* post free, from Mrs Stephens, Alma Road, Rosebank, Cape Town) The magazine is issued by the Cape Natural History Club, and should it meet a demand it will be issued quarterly, or possibly in time monthly

International Hospital Congress

THE Fourth International Hospital Congress, which has been organised by the Italian Government, will be held at Rome on May 5–12, when the following subjects among others will be discussed the hospital as part of a system of public health , the equipment and technical installation of hospitals , the work of the hospital and its protection in times of disaster The Congress will be preceded by a tour of inspection of some of the large towns in northern Italy, and be followed by excursions in southern Italy, Sicily and Tripoli Further information can be obtained from the International Hospital Association, Lucerne, Switzerland

First Comet of 1935

A MESSAGE published in *The Times* of January 10 announces that a comet has been discovered by Mr E L Johnson of the Union Observatory, Johannesburg This comet will be called Johnson's comet, 1935*A* The comet is presumably faint Some half dozen faint comets are seen every year For example, in 1933 there were six, ranging in magnitude at brightest from 8 to 18 (this was the faintest comet which has yet been observed) Of these, three were periodic and recognised as returns of known comets. It is some years since a notable, naked-eye comet appeared

Scientific Meetings in Australia

MANY of the Australian scientific societies have arranged meetings for January in Melbourne, the natural centre during its centenary celebrations for conferences and congresses of all kinds. The Australian National Research Council hold its annual session on January 15, when important questions of future policy were debated It has been suggested that its scope be altered somewhat, and that it take the title of Royal Society of Australia, recently bestowed on a smaller scientific society established at Canberra On January 16–23 the Australian and New Zealand Association for the Advancement of Science is holding its biennial meeting under the presidency of Sir Douglas Mawson Public addresses are being delivered by Dr. P. Marshall on volcanoes of the Pacific and by Sir George Julius on certain aspects of the unemployment problem. Sir David Orme Masson is giving the Liversidge Memorial Lecture to Section B on crucial advances in chemical theory during the last half century Immediately following these sessions, the half-yearly meeting of the Council for Scientific and Industrial Research will take place while many minor societies and groups of workers are arranging gatherings for discussion of matters of common interest

Announcements

THE Council of the Physical Society has awarded the twelfth Duddell Medal to Dr W Ewart Williams, lecturer in physics at King's College, London

WE regret to announce the death, on January 13, of the Rev S. A McDowall, chaplain and senior science master at Winchester College, aged fifty two years

THE Huxley Memorial Lecture of the Royal College of Science, South Kensington, for 1935 will be delivered on May 6 by Sir Henry Dale, director of the National Institute for Medical Research, who has chosen as his subject "Viruses and Heterogenesis an old Problem in a new Form"

THE following appointments have recently been made by the Secretary of State for the Colonies Mr M W Gibbon, Mr J R Miller and Mr E W. Momber, to be superintendents of agriculture, Nigeria , Mr W F Baldock (assistant conservator of forests), to be senior assistant conservator of forests, Tanganyika , Mr C B Bisset (assistant geologist, Nyasaland), to be field geologist, Uganda , Mr A de K Frampton (agricultural superintendent, British Guiana), to be agricultural officer, Straits Settlements and Federated Malay States , Mr G L R Hancock (assistant entomologist, Agricultural Department), to be biologist, Makerere College, Uganda , Mr E F Peck (veterinary officer, Nigeria), to be veterinary and agricultural officer, Somaliland , Mr C Smith (deputy conservator of Forests, Federated Malay States), to be conservator of forests, Johore , Mr A J Wakefield (senior agricultural officer), to be deputy director of agriculture, Tanganyika

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —An agricultural lecturer and warden at the Kent Farm Institute, Borden, Sittingbourne (Jan 21) Teachers of science subjects and mathematics and engineering at the Willesden Technical College—The Secretary, Willesden Local Higher Education Committee, Education Office, Dyne Road, Kilburn, N W 6 (Jan 25) A head of the Junior Technical School for Boys, North-Western Polytechnic, Prince of Wales Road, Kentish Town, London, N W 5—The Clerk to the Governors (Jan 31). A veterinary pathologist in Malta—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S,W 1 (Jan 31) An assistant entomologist at the Rothamsted Experimental Station, Harpenden, Herts—The Secretary (Feb 15) A professor of botany in the Egyptian University, Abbasia, Cairo—The Dean of the Faculty of Science (March 15).

Research Items

Queensland Aborigines. Further notes on the aborigines of Princess Charlotte Bay, North Queensland, have been published by Messrs Herbert M Hale and Norman B. Tindale (*Rec S. Austral Mus*, vol 5, No 2) A study of the language and vocabularies of four tribes are included Two types of canoe are in use, one in which a single outrigger is placed on the starboard side, and the other a double outrigger The canoes are made from trees hollowed out, formerly by axes of stone, and the outriggers are supported by booms In the first, the booms are lashed to crossed sticks which are attached to the outrigger, in the latter the booms are directly attached in pairs to each outrigger The view held by Roth that the single outrigger is a local modification of the double is not accepted It is thought that they are both due to external cultural influence, differing in time. The camps are both temporary and semi permanent The former may be constructed by small parties when away hunting Their shelters differ considerably from those which are erected in the semi permanent camps and may be occupied for weeks or even months. The temporary shelters are semicircular, and only four or five feet in diameter. They are formed of a framework of thin saplings, on which strips of bark are laid Leafy boughs afford additional shelter from the sun In the more enduring form, the huts are larger and higher. They are built in a rounded dome-shaped form with a circular base about ten feet in diameter Bark completely covers the framework, except for the small doorway only twelve or sixteen inches in height The bark is covered with thick tussocks of grass This affords efficient shelter from all but the heaviest rains The only shelters to which the term 'permanent' can properly be applied are caves and rock shelters These are occupied by large bodies of natives for long periods, especially during the wet season The surfaces of large rock shelters usually bear a number of paintings, many representing animals and other objects, which can readily be identified

Ecology of a Bahaman Fresh-Water Lake. An interesting research by Mr C M Breder, Jr, "Ecology of an Oceanic Fresh-water Lake, Andros Island, Bahamas, with special Reference to its Fishes" (*Zoologica*, **18**, No 3, 1934) is the result of short expeditions in January 1932 and 1933 This island represents a certain ecological condition that should be of particular interest to biologists It is truly oceanic and of coral reef formation The fishes in Lake Forsyth have already been listed (Breder 1932) and are the only vertebrate group which may be considered abundant. They are all typically marine, or at least brackish-water forms, and are apparently entirely supported by the dense beds of the peculiar brackish and hardwater plant *Batophora* flooring the bottom of the lake, or by the microscopic or nearly microscopic organisms living on its fronds, a certain number being predaceous and feeding on the former. The fish population in such fresh-waters as those on Andros Island may be accounted for by their ability to withstand fresh-water in which a sufficient amount of calcium is present The few invertebrates present are mostly fresh-water forms, marine invertebrates in general not sharing the adaptability of the fishes and being much more susceptible to slight chemical changes "Lake Forsyth may be considered as representing a 'new' fresh-water environment in which invading forms are just commencing to establish themselves Various gradations from this condition backward to purely marine conditions are represented in other Bahama Islands, Andros Island representing the most advanced position chiefly because of its greater drainage area."

Fish Gills Specialised for Oxygen Deficiency. Accessory respiratory organs in fishes are somewhat seldom, and then in a secondary sense, related to living out of water In all fresh-water fishes with such accessory structures, the development of the structures has been correlated with existence in oxygen-deficient water, as Carter and Beadle notably showed for the inhabitants of the Gran Chaco swamps Gerrit Bovelander has examined *Amia* from this point of view, and notes that the gills are in many respects different from those of other fishes. The lamellæ are highly modified into sieve plates, which are presumably highly efficient in absorbing oxygen under low tension, and possibly serve also in atmospheric respiration (*Copeia*, p 121, 1934) He suggests that this specialisation is correlated with continued existence and activity in stagnant marsh waters, which would explain not only the habitat selection displayed by *Amia*, but also the survival of this 'living fossil' into present times.

Digestion of Wood by Insects. Since Lyonet in 1762 carried out the first crude experiments designed to discover how wood is digested by insects apparently feeding on it, a large number of investigators have attacked this fascinating problem. The history of these researches and the latest conclusions are very concisely surveyed in a recent paper by K Mansour and J J Mansour-Bek (*Biological Reviews*, **9**) The main conclusion is that the rôle in the digestion of wood of intracellular micro-organisms, often present in xylophagous insects, is not so important as was thought by many authors, particularly by Buchner and his school Indeed, some wood-eating insects proved to be free of micro-organisms and yet able to survive on a wood diet, being able to secrete cellulose The micro-organisms of others have been cultivated *in vitro*, and found to be unable to break down cellulose In wood-eating termites, the intestinal Infusoria are utilised as a direct source of food, so that these insects should be classified as feeding on micro-organisms, not on wood Many true wood-eaters do not depend upon cellulose and have no cellulase, but utilise starch and soluble sugars in the wood. Nitrogen is obtained probably from proteins which are practically always present in wood, while proteolytic enzymes have been found in most wood-eating insects. This makes superfluous the assumption that micro-organisms fix atmospheric nitrogen for the use of their host

Wood Anatomy and Angiosperm Origin. Prof. G. R. Wieland has an interesting discussion from the palæobotanical point of view of recent contributions bearing upon this problem in "Tropical Woods" of 1934, the journal published by Prof. Record of Yale University. He deals especially with the new investigations of Hagerup, in which developmental

studies have been made of the conifer inflorescence by the method of serial sections These researches have strengthened the view that the conifer phylum, including both *Pinus* and *Araucaria*, is a very homogeneous group But Wieland dissents from the view that it is a necessary conclusion that the main source of the Angiosperms has to be found along a line from Conifers to Gnetales to Piperaceae and Juglandaceae He recalls again the anatomical resemblances between the Cycads and the Cycadeoids which have been his own main interest, and the Angiosperms, especially those vessel less members, the Homoxyleæ of van Tieghem which are again coming into the forefront of botanical interest Gupta's recent review of the homoxylous woods is examined, but Wieland dissents from his tendency to put *Magnolia* and Cycadeoid into parallel rather than convergent lines Wieland still evidently sympathises with Lemesle's conclusion (*Rev gen de Botanique*) that the Magnoliaceæ are very ancient as compared with other Angiosperms (Lemesle regards the group as showing clear transition from scalariform tracheids to vessels) and that the 'Cycadeoid theory' of Angiosperm origin must still be reckoned with

Cold Weather Planting in Northern India. In Forest Bulletin No 86, "Cold Weather Planting in Northern India" (Delhi Manager of Publications, 1934), Mr H G Champion, sylviculturist at the Research Institute, Dehra Dun, deals with the planting problem in the United Provinces Except where irrigation is an economic proposition, practically the whole of plantation work has to be done at the break of the rains, when the necessary labour is usually very difficult to procure and, even if obtained, is very liable to leave the work or be largely incapacitated by malaria and other complaints due to the general dampness, and to the unsatisfactory condition of the drinking water After an allusion to the *taungya* methods of obtaining new crops, which are proving in some cases so great an assistance, Mr Champion says that were it possible to do any appreciable part of the work in the cold or early hot weather, it would be most advantageous Cold weather work would be of value because, for nearly all species, the most rapid growth occurs in the first week or two of the rains, or even before the monsoon has set in definitely enough for most planting work This period is lost if the plants are only recovering from transplantation or the planting out work cannot all be completed in the very few early favourable days. This is an interesting comment since experiences in West Africa, under rather different conditions, are pointing in the same direction The bulletin describes experiments made between 1927 and 1932 at Dehra Dun on planting out entire plants or stumps of thirty-three tree species after good winter rain, and a few trials of planting at regular intervals throughout the cold weather. As would be expected, the results varied greatly with the amounts of rainfall during the year of experiment, but very few species proved satisfactory. Teak stumps planted in March in the shade give good results provided the monsoon is not delayed, which has happened only twice in the period at Dehra Dun, but they may succeed in most years in more favourable localities

The Alkali Metals. H Alterthum and R Rompe have prepared (*Phys Z*, Oct 15, 1934) a long summary of work done on the alkali metals in the years 1930–33. The summary includes nuclear properties atomic weight, mechanical and magnetic nuclear moments, natural and artificial nuclear disintegration, electronic properties of the atoms and molecules, including spectroscopic data, fluorescence and gas-discharge work, chemical, electrical and optical data of the dispersed and of the massive metals There is a special section on laboratory methods for the preparation of the pure metals The lists of references given should be extremely useful to those working with these metals

Non-Linear Mechanics Three monographs on this subject, by Prof N Kryloff and Dr N Bogoliuboff, have been published at Kieff by the Academy of Sciences of the Ukraine, making a total of seventeen published there or elsewhere since 1931 Some are in French or German, those in Russian or Ukrainian usually have a French summary The general problem is the solution of differential equations relating to motion which is approximately simple harmonic, but not exactly so It is closely related to H Bohr's theory of almost periodic functions, that is, of functions having no periods in the strict sense, but having an unlimited number of them to any given degree of approximation However, the Russian authors are not, like Bohr and many others, concentrating on the purely mathematical and functional aspect, but are developing it from the point of view of differential equations and their physical interpretations Among the wide range of their applications may be noticed astronomy (celestial mechanics), engineering (vibrations of synchronised machines), aviation (longitudinal stability of aeroplanes), and radio-telephony (properties of radio valves) They show that a phenomenon analogous to the Raman effect, which is usually regarded as explicable only by quantum mechanics, can be explained by classical mechanics as a simple consequence of the equations of motion not being exactly linear

Characteristic Solution of a Differential Equation It is well known that an integral equation can be found equivalent to the system made up of a linear differential equation and certain boundary conditions, and that the appropriate Green's function of two variables is closely connected with either system A method of finding an integral equation corresponding to a differential equation without boundary conditions is now given by H Nakano (*Japanese J Math*, 11, 1934) Again a function of two variables plays an important part. It is called the characteristic solution, but it must not be confused with the characteristic functions (of one variable) arising from a differential equation involving a parameter The characteristic solution, unlike the complete primitive of the differential equation, contains no arbitrary constants; but if either is known the other can be easily obtained. Usually, of course, both are unknown, but we can obtain a certain amount of information about the characteristic function by means of an integral equation which can be set up in terms of the functions occurring as coefficients in the given differential equation The author imposes severe restrictions upon these coefficients, and one wonders whether the methods could not have been extended so as to include an investigation of singularities The later part of the paper applies the properties of characteristic solutions to a certain class of differential equations called *volleigentlich*, which may perhaps be translated as 'wholly proper'.

Geographical Studies and Teaching

Geographical Association

THE annual meeting of the Geographical Association was held at the London School of Economics on January 2-5. Lord Meston in his presidential address dealt with the "Geography of an Indian Village", referring particularly to his own experience as a settlement officer in the United Provinces in the early days of his service in the Indian Civil Service.

This careful description of the work of a settlement officer has a great importance as illustrating the use of a thorough local geographical study as a basis for property valuation, taxation and local administration. When the assessment or reassessment of a District (using that term in its Indian sense as meaning an administrative unit, commonly 1,000-3,000 square miles in area) becomes necessary, the work, which is likely to occupy three or four years, is entrusted to a 'settlement officer'. He starts by securing a general view of the whole area, and in the careful descriptions prepared there exists, hidden away in Government offices throughout India, a vast store of unpublished material of great geographical value. He then undertakes systematically the survey of each village—a 'village' designating the tract of land (in the United Provinces commonly 50–1,000 acres) round the hamlet or residential centre. A base map—usually on the scale of 16 inches to one mile—is prepared either by the Survey of India or by an *ad hoc* survey party controlled by the settlement officer. Each field is numbered and a description of it made by the village accountant. The record includes the character of the soil, crops, ownership, occupation, taxable value and taxes paid. The soil classification commonly used is into black cotton soil, first-class loam, second-class loam, sandy loam, sand, gravel and uncultivable. It is not perhaps fully realised that there exists for practically the whole of settled India this accurate soil and land utilisation survey.

The nucleus of the older type of Indian village in the United Provinces is usually the ancestral home of the chief landowner surrounded by its mud wall. Around it is an irregular ring of houses—arranged with very little planning and no sanitation, then the hovels of the depressed classes. The village pond, which serves as a public bath for man and beast as well as for a supply of drinking water, completes the picture. Surrounding the hamlet is a ring of richly manured land but which, because of the source of its manure, is only cultivated by the depressed classes, and then finally the arable land of the villagers. Reference was made by Lord Meston to changes in soil and soil values which are tending to result from the extension of irrigation—including the impoverishment consequent upon the accumulation of alkali.

Two sessions of the Association were held in conjunction with the Le Play Society. At one, Mr. A. E. Moodie gave an account of studies carried out in the Stubaital in the Austrian Tyrol. At the other, under the chairmanship of Sir John Russell, the leader of the party in the field, three short papers were presented on Russia. Mr. R. A. Pelham gave a historical introduction, Dr. A. S. J. Baster, an economist's view, while Mr. Leonard Brooks gave a fascinating account of recent educational developments. He emphasised the central place that the factory occupies in the life of a community and that, like other activities, the school is attached to it. As vocational education, the system is good in the essentially close contact which is maintained. The children are given a conspectus of the whole working of the factory, and can afterwards take their places in different parts of the works. Similarly, the university has almost entirely given place to specialised technical research or training institutions. There are already signs, it would appear, of the desire to return to a more general educational system, at least in places, but the general progress in literacy made in the last five years is so amazing as to be almost incredible.

Dr. G. P. Gooch in his address on "Geography and International Problems" indicated clearly the importance attached by historians to the geographical background, but at the same time illustrated the need for closer co-operation between specialists. His sketch of the geographical background of China could not possibly be accepted by geographers, nor could his description of the Saar.

Dr. Dudley Stamp in his lecture on "Planning the Land for the Future" referred particularly to recent studies in land utilisation in the United States. At present, out of a total area of 3,000,000 square miles, the proper use of roughly a third is not yet decided. For the best types of land in the country—for example, the belts of good soil in the Middle West—it is clear that they must remain in agriculture. Similarly, for the poorest lands the proper use is clearly desert, forest or grazing. The problems arise in areas of intermediate value. Amongst the reasons for existing mal-utilisation of land some of the chief are: (*a*) those consequent upon the history of settlement—the clearing of poor land in the East before the better land was discovered; (*b*) the ravages of soil erosion; (*c*) the development of communications throwing all areas into ready contact and rendering cultivation in poorer tracts uneconomic; (*d*) 'over-production' of agricultural commodities consequent upon technical progress combined with diminution of foreign trade; (*e*) the depletion of forest lands; and (*f*) social changes—the need for more land for recreation or for semi-subsistence cultivation. A summary was given of work undertaken, especially under the Roosevelt administration, to combat the difficulties. Of the varied planning schemes, those based on the economic needs of the moment are fraught with danger; those based on a careful investigation of the potential capacities of the land are working on a sure foundation.

Among the interesting lectures of a general nature must be mentioned that by Brigadier H. St. J. L. Winterbotham on the history of the Ordnance Survey, Dr. Bernard Smith on water supply and Dr. Allen Mawer on place name study.

Institute of British Geographers

The formation of the Institute of British Geographers was recorded in NATURE of January 14, 1933, and the Institute held its third annual meeting at the London School of Economics on January 1 and 4 of this year.

Dr. H. A. Matthews dealt with the "Seasonal Distribution of Rainfall in the Mediterranean Region of California" by a careful analysis of dispersion

diagrams The results, in this area, confirm the general simplicity of the regime and do not therefore add greatly to the information obtained by using mean monthly rainfall values, but a clear demonstration is afforded of the value of a logarithmic scale in plotting seasonal variation Variability of monthly precipitation increases markedly (a) from north to south and (b) from lower to higher elevations

Mr E G Bowen showed the results of attempting to map the 'spheres of influence' of the missionary saints of the Dark Ages, choosing St Samson and St Columba, in Celtic Britain These spheres seem to coincide with cultural provinces determined on the basis of archæological distributions, but in the discussion various reasons were suggested for this Mr K H Huggins's paper on "Types of Settlement in the Scottish Highlands" was concerned to a considerable degree with the delimitation of the Highlands' as distinct from the 'Lowlands' By using such criteria as structure, elevation, 'amount of relief', proportion of moorland, type and density of settlement, different 'limits' to the Highlands are obtained, and there is clearly a central area where all the Highland characteristics are present, fringed by a broad transitional area

Mr K C Edwards dealt with the consequences of recent improvements in the River Trent as a waterway—including the growth of Nottingham as a leading distribution centre for petroleum products

The distribution of settlements, permanent and temporary, and of cultivated crops in Alpine valleys, is a subject of considerable importance and concerning which there is an extensive literature But an important advance in knowledge is marked by Miss Alice Garnett's careful and suggestive study of insolation A formula for the calculation of insolation intensity at any given spot (based on slope, aspect and the sun's elevation) has been devised and it is possible to construct 'intensity maps' Special importance is attached to spring noonday intensity values At the same time 'time periods of insolation' are mapped and the results are combined.

This method of investigation seems to demonstrate a possible law of alpine settlements, namely, that above c 1,100 m, all permanent settlements avoid the areas of winter shade, while *ubac* villages follow the *edge* of the winter noonday shadow line For regions studied in lat 46° N, above 1,400 m, wheat, barley and rye require at least an 80-90 per cent spring noonday intensity Wheat can ripen up to c 1,600 m. where a noonday equinox intensity exceeds 90–95 per cent of the maximum possible at that time, provided these areas also have long time periods of insolation Areas with a 50-70 per cent intensity are generally given over to meadow, while land with an intensity value of less than 50 per cent is left to forest It is abundantly clear that this study has an important bearing on land planning in alpine areas and is capable of extension to regions of lower relief in higher latitudes—for example, to the Highland valleys of Scotland and Antrim, where the intensity and time period of insolation would seem to have a bearing on health problems

Dr S W Wooldridge, by a preliminary analysis of areas in the London basin, dealt with the 'facet' as the ultimate unit of geographical analysis The facet is difficult of definition though the concept is clear A river terrace, a dip slope, a plateau (even if only a fragment) are 'facets' which thus correspond in general with geomorphological units, but in detail have different boundaries Thus the 'Taplow Terrace facet' as a geographical unit does not coincide with the distribution of the Taplow Terrace gravels of the geological map

The last session of the meeting was devoted to a discussion of Prof C B Fawcett's paper on the relations between the advance of science in geography and the life of the community, read before the British Association at Aberdeen in September last.

The Institute, in accordance with its avowed policy of publishing memoirs too long for inclusion in existing periodicals but unsuitable for publication in book form, has issued, as its first volume, Dr R O Buchanan's study of the pastoral industries of New Zealand L. DUDLEY STAMP

Annual Meeting of the Mathematical Association

THE annual meeting of the Mathematical Association was held at the Institute of Education, London, W C 1, on January 7–8, under the presidency of Prof E H Neville, of the University of Reading The following distinguished mathematicians were elected honorary members of the Association: Profs E. Borel (Paris), J Hadamard (Paris), G H Hardy (Cambridge), D E Smith (New York), E. T Whittaker (Edinburgh) Mr. A W. Siddons, of Harrow School, was elected president of the Association for the forthcoming year

In his presidential address, entitled "The Food of the Gods", Prof Neville dealt with a problem in mathematical education which is of considerable importance and difficulty. From the fact that the preparation given to a schoolboy a quarter of a century ago for an entrance scholarship examination at Cambridge would be adequate to this examination as it is at present, while the undergraduate of those days would find many of the questions in a modern tripos incomprehensible, he deduced that the universities of to-day build a different mathematical structure, but are content to build it on foundations which have not changed since the beginning of the century Since this difference is due to the direct influence of changes in emphasis in creative mathematics on the teaching at the universities, he urged that such changes ought to have a greater and far more rapid influence on teaching at the schools than they seem to have. Room for new ideas can only be found by omissions or condensations, by the expulsion from the curriculum of methods and ideas once valuable but now outworn, kept in place through inertia To demonstrate the possibility of such a reform, Prof Neville gave some examples illustrating the successful working of a similar process at the undergraduate stage. To bring this about at the school stage, the young teacher has the knowledge of what is important, the old teacher has the experience of what is practicable and the influence to effect the changes he desires, and Prof. Neville sees in this an opportunity for the generations to co-operate At present, each advance is followed by a score of years in which the backward schools and the popular textbooks creep up to the leaders, he envisages a responsiveness everywhere to the ferment of current ideas, which should result in a mathematical nourishment requiring no long periods of accommodation, the true 'food of the gods'.

Following the presidential address, Brigadier H St J L Winterbotham, Director-General of Ordnance Survey, spoke on "Geography and Mathematics", detailing the many and various ways in which a knowledge of mathematics assists geographical progress

Of the four papers which occupied the morning of January 8, that which attracted most attention was given by Mr C L Parsons, of Merchant Taylors' School, under the title "The Work of a Junior Mathematical Association" The members of this Association are some eight public schools in the London area, five meetings are held each year, and a good attendance of the mathematically minded pupils in the higher forms of these schools is obtained Occasionally the meetings are addressed by distinguished adult mathematicians, but more frequently by the boys themselves, who are thus encouraged in habits of independent thought and research Sir James Jeans is the president of the Association, and the president's annual essay prize attracts many excellent entries

In the afternoon, Prof D R Hartree, of the University of Manchester, gave a paper on "The Bearing of Statistical and Quantum Mechanics on School Work"; after asserting that the new mechanics has no direct bearing on school work, he explained in elementary terms some of the basic concepts of the subject in such a way as to illustrate the indirect influence the new ideas might be expected to exert on school work in mathematical physics Following this, the warm interest which members of the Association invariably take in points of teaching practice was again demonstrated by a lively discussion on "The First Encounter with a Limit", in which teachers from the schools and universities took part The meeting ended with a delightful lecture by Prof G H Hardy on "The Theorem of the Arithmetic and Geometric Means", in the course of which he discussed several different proofs of the fundamental inequality connecting these two means, and incidentally directed attention to some very important, but much neglected, work by Dr R F Muirhead on inequalities of a more general type

Work of the Rothamsted Experimental Station

As knowledge of plant growth accumulates, the number of points from which the problem of crop production can be attacked increases Since the foundation of the Rothamsted Experimental Station in 1843, the activities of the Station have been steadily extended so as to make it possible to follow up some of the new problems which are continually brought to light by the work there and elsewhere The study of quality *in crops, for example*, has led to a considerable amount of work in conjunction with the Institute of Brewing, the Millers' Research Association, sugar beet factories, etc The work on malting barley, for example, has outgrown the accommodation at Rothamsted, and, having reached the stage where closer contact with the brewing industry was necessary, has been transferred elsewhere

The Rothamsted report for 1933* gives a brief summary of the various problems under investigation during the year at Rothamsted and Woburn, and also includes trials carried out at outside centres. Though the field and laboratory work are really one, they are, for the sake of convenience, dealt with separately in the report The report includes results of some schemes of experiments conducted on a uniform basis at a number of centres, for example, results of ten years experiments with malting barley, and of experiments on the effect of fertilisers on the yield and quality of sugar beet A list of papers published from the Station is also included, together with comments on the contents of each

The problem of soil organic matter continues to receive attention, the plan of investigation being one designed and begun some years ago This problem is important in view of the possibilities of mechanised cereal growing, and the Rothamsted experiment will help in answering the question which will inevitably be asked by those contemplating farming under the new conditions—how far it is possible to practise mechanised corn-growing and pay no attention to replenishing the stocks of soil organic matter by the addition of farmyard manure, sheep folding, etc

* Rothamsted Experimental Station, Harpenden Lawes Agricultural Trust Report for 1933 Pp 200 (Harpenden Rothamsted Experimental Station, 1934) 2s 6d

That the solution of this problem is not so simple as was once considered is gathered from the observation in the report that green manures do not keep up the productiveness for wheat of the light soil at Woburn, and that the residual values of farmyard manure and of cake and corn fed to animals at Woburn appeared to be much less than is indicated by the recognised tables The latter observation has also an important bearing on the existing *method* of *assessing* certain compensations due on the termination of tenancies.

Dr R A Fisher, who left in October 1933 to take up his new duties as Galton professor in the University of London, has written a short account of the contribution of Rothamsted to the development of the science of statistics. One development, namely, the realisation that it was necessary to treat the question of field procedure and that of statistical analysis as but two aspects of a single problem, has resulted in definitely increasing the value of experimental work To quote Dr. Fisher, "By applying statistical methods not only to the interpretation but also to the design of experiments, it is not uncommon for the value of the experiment to be increased five or ten fold, a result which could not be obtained from improved methods of interpretation only" It is doubtful, for example, if the capacity of superphosphate and sulphate of ammonia for reinforcing each other's effect could have been detected and estimated if it were not for the improvements in plot technique and interpretation of results The Statistical Laboratory has tackled the problem of technique in livestock trials, having commenced by a successful pig feeding experiment; the pens and feeding arrangements have been designed so that all types of rations are distributed equally over all the groups of pens instead of all the pigs on one treatment being in the same pen.

The report is essential for those engaged in teaching or research work. The long-term experiments and the thoroughness of the liaison between field and laboratory work give added value to the work at Rothamsted The practical farmer will also find the report interesting, but most of the results will doubtless reach him through the medium of the agricultural Press.

University and Educational Intelligence

LIVERPOOL.—Prof. H. H. Read, George Herdman professor of geology, who has just been awarded the Bigsby Medal of the Geological Society of London, has worked largely on the geology of the Highlands. He has made a number of important discoveries on the complicated region of lower Banffshire and north Aberdeenshire, and has just published a paper on the geology of Unst, in the Shetland Islands.

EDUCATIONAL problems in India are, perhaps, more various and more baffling than in any other country, and among the most difficult are those of the education of the Anglo-Indian child. Also, at the present time, they are of peculiar urgency owing to the progressive limitation in recent years (and the prospect of still more drastic limitation in the near future) of the fields of employment open to the Anglo-Indian community and the simultaneous increase (from 1921 until 1931, 22 per cent) in their numbers: some 20,000 who ought to be earning their living are actually unemployed. A valuable and timely discussion of the subject is reported in the *Journal of the Royal Society of Arts*. A paper read on November 9 before the Indian Section of the Society by the Very Rev. J. A. Graham, honorary superintendent of St. Andrew's Colonial Homes, Kalimpong, Bengal, describes what has proved to be an efficient enterprise for enabling needy Anglo-Indian children to develop into worthy members of society. Beginning in 1900 with six children, it has grown into an educational colony in which 575 boys and girls housed in cottages are being trained for such occupations as agriculture, engineering, the railway, telegraph and forest services, business, teaching and nursing. In the course of the discussion which followed the reading of the paper, attention was directed to the recent inauguration of a ten thousand acre colony at Lapra in Bihar. This was described as one of the most hopeful of projects hitherto tried for providing openings for Anglo-Indians.

Science News a Century Ago

Translation of Cuvier's "Animal Kingdom"

Cuvier's "Animal Kingdom", which had been published in fifteen volumes by Edward Griffith and others, was reviewed at length in *The Times* of January 24, 1835. The whole of the Baron's "Règne Animal", said the reviewer, has been translated with a vast addition of supplementary matter, including a full description of all the species, calculated to render the work "not merely useful to the naturalist, as a book of pure science, but also interesting to the public at large, as a general zoological biography, and ornamental as containing original and well executed illustrations. . . . The gentlemen who have been associated with Mr. Griffith in this arduous undertaking are Mr. Edward Pidgeon, Colonel Charles Hamilton Smith, Mr. John Edward Gray and Mr. George Gray. Their competency and qualifications are sufficiently well known. . . Without entering into a more elaborate examination of the work, we may confidently characterise it as one which cannot fail to recommend itself to a very high rank in public estimation. It appears to have been executed with great care; it evinces a large share of scientific talent and research in the editors; and the plates, some of them from drawings by Landseer, are distinguished by great neatness and fidelity."

Of the authors of this work, Griffith (1790–1858) was an original member of the Zoological Society, John Edward Gray (1800–75) was a keeper at the British Museum and Col. Smith (1776–1859) served in the Army in 1797–1820. After the appearance of the review, a correspondent wrote to *The Times* saying that Edward Pidgeon had died in poverty on October 14, 1834.

Beaufoy's "Nautical and Hydraulic Experiments"

Col. Mark Beaufoy (1764–1827), the son of a Quaker brewer, was a physicist and astronomer, but he will be remembered longest for his experiments on ship resistance, and as the founder in 1791 of the Society for the Improvement of Naval Architecture. His experiments were made in Greenland Dock, Rotherhithe, during the period 1793–98. After his death, his son published at his own expense his "Nautical and Hydraulic Experiments with numerous Scientific Miscellanies", the book being printed at Beaufoy's private press in Lambeth. In a review of the first volume of this work published in the *Athenæum* of January 24, 1835, many passages were quoted. One of these said: "For some years the calculations were made at Colonel Beaufoy's residence at Hackney Wick by himself, assisted by his wife, who contributed no inconsiderable share to the progress and success of the experiments; for favoured alike in person and in mind . . . she was a good mathematician and astronomer familiar with all the details of the observatory, the calculation of eclipses, etc. . . . she was never at a loss for leizure in the furtherance of her husband's pursuits."

In concluding his remarks, the reviewer said, "we have only to express our obligations to the publisher for the munificent gift he has laid on the altar of science. By the time his work is completed, it will, it is reported, have cost together with the experiments it records, a sum of 60,000£, the value of thirty years assiduous labour not being counted in this estimate. There is a munificence and devotion about this gift, which have, we believe, no parallel in the history of science."

Records of General Science

In January 1835, the first number appeared of a *Record of General Science*, a monthly journal edited by Dr. R. D. Thomson, lecturer in chemistry in the Blenheim Street Medical School, with the assistance of Prof. Thomas Thomson, regius professor of chemistry in the University of Glasgow. It was published by John Taylor, 30 Upper Gower Street, London, bookseller and publisher to the University of London. In the preface, after some remarks on the general history of periodicals, it was said: "A few years have only elapsed since not less than six Scientific Journals were published in Great Britain; these have now dwindled into two one of which is published monthly in London, and the other quarterly in Edinburgh". The number opened with an article by Prof. Thomas Thomson "On Calico-Printing", illustrated with actual samples of material pasted in. Other articles dealt with respiration, the composition of the blood, vanadate of lead, transmission of heat through bodies, distillation of pit-coal and the magnetic intensity of the earth. Some of the articles were original contributions, while others were reprinted from the leading scientific journals published on the Continent.

WAVRE The representation of certain uniform functions W SCHOPFER Action of growth factors contained in urine The action on a micro-organism. The author shows that normal human urine contains a substance, differing from the usual substances and acting as a growth factor for a micro organism This substance is soluble in ethyl alcohol, dilute acetone, methyl alcohol and chloroform but insoluble in ether and benzene It is thermostable and is adsorbed by animal charcoal It differs from auxine and may arise from plant food

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Sunday, January 20

BRITISH MUSEUM (NATURAL HISTORY), at 3 and 4 30 —M A Phillips "Fossil Reptiles" *

Monday, January 21

KING'S COLLEGE, LONDON, at 5 30 —Prof G Temple "The Theory of the Radiation and Reception of Electro-Magnetic Waves by Aerials (succeeding lectures on January 28, February 4, 11, 18, 25, March 4 and 11) *

ROYAL GEOGRAPHICAL SOCIETY, at 8 30 —Martin Lindsay "The British Trans Greenland Expedition of 1934"

Tuesday, January 22

BRITISH INSTITUTE OF PHILOSOPHY, at 8 15 —(at University College, London, W C 1) —Sir Herbert Samuel "Philosophy, Religion and Present World Conditions" * (Ticket)

Wednesday, January 23

GEOPHYSICAL DISCUSSION, at 5 30 —(Joint meeting with the Geological Society in the rooms of the Geological Society, Burlington House, W 1) "The Hypothesis of Continental Drift", to be opened by Dr W B Wright

ROYAL SOCIETY OF ARTS, at 8 —C L Burdick "Humidity, Health and some New Inventions"

Thursday, January 24

QUEEN MARY COLLEGE, at 5 —Prof W N Haworth "The Molecular Structure of Carbohydrates" *

Friday, January 25

KING'S COLLEGE, LONDON, at 3 15 —C. J Jadd "Babylonian Ideas of the Relations between Gods and Men" *

ROYAL SOCIETY OF ARTS, at 4 30 —C Ranganatha Rao Sahib "Recent Industrial Progress of Mysore"

ROYAL INSTITUTION, at 9 —Sir Richard Livingstone "Ancient Greece and Modern Civilization"

CONTENTS

Evolution and Human Origins

EVERY year brings to light evidence which implies a far greater ambiguity for man than that given to him in the book of Genesis The caves of Mount Carmel, for example, have quite recently been found to contain deposits, fully sixty feet in thickness and laden with fossil bones of man and beast, to say nothing of a succession of stone implements The ancient Palestinians represent a breed of the extinct Neanderthal species, the stone tools are of the kind used in Europe long before the onset of the last glaciation Even more revolutionary are the contributions which Africa is now making to the solution of the problem of man's origin East Africa is proving to be particularly rich in deposits laid down during Post-Pliocene times In the oldest of these deposits, Dr L S B Leakey has discovered crudely worked hand-axes, on the overlying beds he has traced a gradual refinement of this type of tool He has also found fragments of the East African tool-makers Yet the oldest of these deposits were laid down at least half a million of years ago So it has been with every part of the Old World China, Java, Australia, Italy, Spain, France, Germany, Belgium and England, each has contributed its quota of evidence

Why is it that all the anthropologists who have had to interpret the evidence of these discoveries, have presumed that the theory of evolution is true, and that the Mosaic tradition is wrong? The first reason is that the Biblical background of time is too restricted, the evidence now at the disposal of anthropologists requires a time-scale which runs into hundreds of thousands of years The second reason for the rejection of special creation as a manner of origin, is man's mode of development He arises, as do all other vertebrates, from a fertilised egg his development within the womb is almost identical to that pursued by the great anthropoids Piltdown man, Heidelberg man, *Pithecanthropus* (Java man), *Sinanthropus* (Peking man), and Rhodesian man, have never been regarded by anthropologists as special creations they have presumed that such fossil specimens were twigs which had fallen from the evolving tree of humanity They have made many attempts —most of them purely tentative—to reconstruct man's evolutionary tree

Anthropologists are prepared for criticism directed against the form they have given to their trees of human evolution, but they did not

anticipate that anyone would attempt to sweep out of existence their evidence and the superstructure they have built on it This, however, is what *has* happened Sir Ambrose Fleming, in his presidential address* on January 14 to the Victoria Institute, asserted 'that this sedulously propagated hypothesis of man's age-long evolution by Darwinian Natural Selection is the product rather of the imagination than based on indisputable evidence . The cardinal error is that it substitutes as the ultimate source of all things an impersonal self-acting or automatic process of improvement, in place of the Will and Power of a personal, Self-conscious Creator and Father of Mankind *Adherence to the doctrine of evolution is entirely inconsistent with belief in the fundamental doctrines of Christianity* " We have italicised the last sentence of this quotation because it seems to us that Sir Ambrose has loaded his dice very heavily against those who believe in evolution

How, then, does Sir Ambrose deal with the evidence on which the anthropologists have built so much ? First he sweeps away their time-table, he describes it as an "unjustified assumption" and as a "guess" Yet it is the kind of "guess" we all make daily when we seek to assess the age of the man, woman or child we may pass on the street We have no difficulty in distinguishing between the ages of a boy of ten and a man of fifty Geologists and anthropologists will certainly be astonished by Sir Ambrose's assertion that the history of *Homo sapiens* can be fitted into the calendar of Biblical dates He prefers the chronology of William Hales, who assigned the creation of Adam to the year 5411 B C to that of Archbishop Usher, who gives 4004 B C as the eventful date He regards "the palæontological or fossil evidence" as being "painfully small" He makes short work of the "discoveries" on which students of man's origin rely so much "The few scattered remains represented by the Java, Heidelberg, Piltdown and Pekin 'man', as far as they are not truly animal may rather be regarded as biological abnormalities or cases of decadence rather than stages in an upward development "

Having dismissed these fossil remains from his consideration, Sir Ambrose is left with only two early forms of humanity to be fitted into the inspired scheme of special Creation—namely, Neanderthal man and Cro-magnon man The latter he hails as real sons of Adam, he recognises in them the moral and spiritual attributes of true man Seeing that the Cro-magnons appeared in Europe long before the ice-age had ended, and that Sir Ambrose admits that "there is evidence not altogether negligible that a last glacial epoch may have ended not much more than seven to ten thousand years ago", it is difficult to see how they could have made their way into Europe from the Garden of Eden if the event of man's creation di . occur at the date postulated by him, namely, 5411 B C He apparently forgets, also, that the evidence from Egypt indicates that men were not only living in the valley of the Nile at that time, but were already sowing and reaping, spinning and weaving and burying their dead in the expectation of a life hereafter, for how otherwise can we explain the 'goods' which are found in the graves of the early Egyptians

Very different is the position which Sir Ambrose assigns to Neanderthal men, who were in existence before the onset of the last glacial epoch. He refuses to regard them as true men, he maintains that they were destitute of "the mental and spiritual power" of true men In this he is not just, for one of the most representative specimens of this species of extinct humanity, namely, the man of La Chapelle, was buried with weapons and food—which we may justly interpret as evidence of a belief on the part of his people that the dead had a life when the earthly one was over

In connexion with the origin and nature of Neanderthal man, Sir Ambrose puts forward a "view" which raises a very interesting question. Is it permissible to alter in even the slightest detail the inspired word of the Bible ? To do so is to bring the "inspired word" down to the level of a scientific hypothesis, for it is of the nature of a hypothesis that it may be altered to meet fresh facts as they arise "There is another view," he said, "which may be put forward very tentatively and that is that between the anthropoid apes and true man with his psychical and spiritual as well as bodily structure, there *may* have been some species of hominoids created with more than ape intelligence, but not 'man' in the sense of the word used in the Bible " This view is put forward as an alternative to the "view" that Neanderthal man is a degenerate form of true man Sir Ambrose's critics may fairly complain that he has gone beyond any justification obtainable from the Mosaic record They may also complain that he cites only one version of the creation of man from

* Modern Anthropology *versus* Biblical Statements on Human Origin By Sir Ambrose Fleming Pp 25 (London Victoria Institute, 1935) 1s.

the book of Genesis—namely, Genesis, i 26 "Let us make man in our image, after our likeness" The fact that the book of Genesis is a composite work, and that it includes two versions of creation derived from separate sources has, of course, long been recognised by Biblical scholars More instructive than the above version is the different description of the creative act given in Genesis, ii 7, "and the Lord God formed man of the dust of the ground, and breathed into his nostrils the breath of life, and man became a living soul" We should have expected, too, mention of the manner in which Eve came into being, and how the prediluvial population of the world had arisen from a single pair

We are sure that Sir Ambrose Fleming would not wilfully misrepresent the case of his opponents, yet there is no doubt he has been unfair to the Bishop of Birmingham "There are," said Sir Ambrose in his lecture, "no sufficient reasons for declaring the evolutionary origin of the human race a definitely certain fact Certainly none for assuring a general congregation in Westminster Abbey, as did Bishop Barnes, on Sunday, Sept 25, 1927, that 'To-day there is among competent men of science unanimous agreement that man has been evolved from an ape-like stock'" In so far as anthropologists were unanimous in 1927 as they are to-day in regarding man as a product of evolution and not of special creation, we hold that the statement made by the Bishop of Birmingham was amply justified We rejoice, too, to note that the new dean of St Paul's, Dr Matthews[1], supports the evolutionary doctrine of man's origin and in opposition to Sir Ambrose Fleming sees no incompatibility between the doctrine of evolution and the precepts of Christianity

[1] *Daily Telegraph*, Jan 18, 1935. "Evolution and the Human Race"

Malaria in Ceylon

THERE is unfortunately no doubt about the serious nature of the epidemic of malaria in Ceylon. The telegrams in the Press report that in the affected provinces no less than 3,435 deaths from malaria and fever occurred during the month of December, compared with a monthly average of 531 for the first nine months of the year It is admitted, however, that these figures are not final It has been reported that there have been more than half-a-million cases of malaria, and if the death-rate was 5 per cent, that would give us something like 25,000 deaths

The first need in an outbreak like this is medicine and food, and the Government of Ceylon has been in the happy position of being able to draw supplies of quinine from both India and Java There is, however, another greatly complicating factor, and that is famine The drought which has prevailed—and is generally regarded as the cause of the epidemic—has led to a serious failure of crops, and, even if the rain had not failed, the people themselves have been so weakened by disease that they have not been able to cultivate their fields We may therefore expect that, in a people weakened by want of food and by malaria, this epidemic will be followed by a serious outbreak of dysentery and a rise in the general death-rate from all causes

The epidemic itself has not been caused as epidemics frequently are by the introduction of non-immune people into a malarial territory The outbreak is in a part of Ceylon which is normally healthy The new factor has in all probability been an increase in the number of mosquitoes Among any healthy population in the tropics there is always a certain number of people carrying the infection, and when, as appears to be the case in Ceylon, there is a large increase in the number of mosquitoes, it is easy for the mosquito to acquire infection and to start a serious epidemic Once a mosquito is infected it remains infected for life, and, further, as this epidemic is occurring among people who are not accustomed to malaria, the epidemic is so much the worse

Valuable entomological work has been done in Ceylon by the Government Entomologist, but in view of this great epidemic there must be a full reinvestigation Until we get that, everything is necessarily speculative

One hypothesis is that, owing to the drought, rivers are not flowing so rapidly as they usually do, pools remain in the rocky and sandy beds, and *A culicifacies* is breeding profusely That may be so, but we must not forget that there are some thirty species of *Anopheles* in Ceylon and that they include species of the *A minimus* group and *A maculatus*, which in other countries are important carriers of malaria A grave mistake might be made if a full investigation is not made into what mosquito, or mosquitoes, have been the active agents in producing this epidemic in the various parts of Ceylon to which the epidemic has spread

Obviously the people of Ceylon were not

prepared for a great epidemic, it will be necessary for them to take stock of their position The ancient cities buried in the jungle are a reminder that malaria is no new disease in Ceylon Governing authorities should ask themselves Have they used the knowledge that Ross gave them to the fullest possible extent, or have they made no special effort, thinking that nothing could be done ?

Clearly some sort of inquiry will inevitably be held, but what is required is not so much a search for a scape-goat or an inquest, as a constructive scheme for the future, built on a sure scientific foundation

Reviews

Newton's *Principia*

Sir Isaac Newton's Mathematical Principles of Natural Philosophy and his System of the World Translated into English by Andrew Motte in 1729 The translations revised, and supplied with an Historical and Explanatory Appendix by Prof Florian Cajori Pp xxxv + 680 (Cambridge At the University Press, 1934) 35s net

ANDREW MOTTE'S translation of the "Principia" is not so well known as it deserves to be It was supplied to his brother, the publisher, soon after Newton's death One might expect it then to be no more than a publisher's hack work, of which we have so many dismal examples But Motte appears to have understood the "Principia", and his language does not date noticeably, and never falls below a good level The present work is really a republication of Motte, with some improvements, and—it is regrettable to add—one most serious omission

Prof Cajori died in 1930, so that the book has been seen through the press by Prof R T Crawford, of the University of California, Berkeley But the changes in Motte's text, the notes, and the work generally, is credited to Cajori. The notes seem to be complete, but might perhaps have been put into a compacter form, had the author lived In their present shape, they give a certain number of references, but scarcely advance any of the subjects Along with the "Principia" is a translation of the lectures given at Cambridge and called "The System of the World", which Prof Cajori, apparently with good reason, also puts down to Motte It is quite worth presenting, for, though it is not so complete as the "Principia", it is less guarded and less austere

One distinct improvement upon Motte is found in printing the diagrams among the text, as they were in the various editions of the "Principia". Motte, no doubt in the interest of economy, collected them together and put them into folders Most of Prof Cajori's changes are modernisations. One requires to think a little, now, before one remembers the meaning of "sesquiplicate ratio" and the like But nothing can be done to improve the awkward, old analysis, nor is Prof Cajori quite consistent Thus [*quantitas*] *genita*, retained by Cajori as "a *genitum*", is simply what we now call a function, and "square or cube sides" for "*latera quadrata, latera cubica*" is retained where the modern equivalent would be square root or cube root Nor does he always correct Motte's mistranslations In Newton's celebrated experiment upon apparent and absolute rotation, *situla* means a bucket, whereas Motte translates it a vessel, and Cajori retains this It is a pity that the work did not fall into the hands of a stricter scholar

But these are minor matters The risk of a translation is that it may be more obscure than the original The "Principia" was considered a hard book by people of the time, and Newton deliberately refused to make it more popular In many places he wrote with the extremest compression An example is the Second Definition, which runs "*Quantitas motus est mensura ejusdem orta ex velocitate et quantitate materiae conjunctim*" This figures here—scarcely changed from Motte—as "*The quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjointly*" This seems to me more obscure than the Latin original The comma and the 'the's have spoiled it As one pores over the original words, one reflects that Newton was a geometer, who said, when he pleased, everything at once, so that all parts of his statement must be taken together Newton picked his words, and in many places one will prefer to see what Newton himself wrote, not what Motte or Cajori made of it

Yet the book is a pleasant book, and to the large but not universal class who read English more easily than Latin, it presents distinct advantages in finding one's way about It is doubtful whether it will be read by so-called 'students', which may be taken to mean young men in a hurry The great defect of the book is that it has not an index. A fairly good index was added to the second edition, and Motte gave one too, but Cajori has suppressed it There are multitudes of details dealt with here, some of them most unexpected, such as remarks upon the finite velocity of light, and significant both for what Newton said, and what he did not say In fact, the "Principia" must be easily the most

interesting scientific book ever written It is nearer to our own time than Euclid's 'Elements" Besides, those that have read Sir Thomas Heath's translation and notes on the original text know that the versions that have reached us are very much doctored

The original "Elements" were not at all a school book, but were of philosophical intention, and most of the questions treated by Euclid are now uninteresting The "Principia", on the other hand, besides being the bible of the modern scientific method which has now overrun the whole world, discusses a host of questions that are still alive A short reminder of its contents proves this It begins with a brief philosophical discussion Newton is always briefest when he has thought most and has made up his mind Then the laws of motion The principles of dynamics, including some significant forecasts Absolute and relative rest The interpretation of Kepler's laws The geometry of conics The calculus The law of gravitation Detailed inferences as to the disturbances of the sun and moon upon the earth—one of the propositions has as many as twenty-two corollaries, many of them of lasting importance Resistance of bodies The form of the "body of least resistance" Many detailed and admirable descriptions of experiments The velocity of sound Some important reflections upon light Applications of the law of gravitation to the heavens. The proof that it is gravity which retains the moon in its orbit The precession of the equinoxes. The tides The lunar theory, giving a very adequate calculation of the variation and of the motion of the nodes, and a less adequate calculation of the change of excentricity and the motion of the apses The motions of comets, showing that they obey exactly the law of gravitation Numerous personal references Numerous general scholia, containing remarks at large upon all kinds of questions, such as the relations of the Deity to human affairs.

This is a brief and imperfect list, but it will serve its purpose Surely never was such a torrent of thought produced by eighteen months' work The main points may have been ready before, but many of the details must have been added as the book was written No one really knows what may be in the "Principia", and one is likely to forget one part while one puzzles over another, deciding whether Newton was right—for there are inevitably a good many errors—and picking out the gems of profound thinking from the old-fashioned analysis and mode of expression Not to give an index to a book like this largely defeats the purpose of the volume. The original index ought to have been enormously extended in place of suppressing it altogether. One would willingly have sacrificed the fifty pages of notes for the purpose

Motte did not try his hand at Halley's verses In the second edition, Bentley touched them up, improving their latinity, I suppose, but I prefer them as Halley left them They are worthy of the book, and of the part Halley played in producing it The eloquent passages seem to me to have been meant Here we have a translation by "Leon J Richardson, Professor of Latin in the University of California" It is a poor affair and gives no evidence that the writer knew what he was talking about "*Cur remeant nodi curque auges progrediuntur*" was left untouched by Bentley, but does not figure here—the evil-minded may suspect that Prof Richardson did not know that the apses moved forwards and the nodes backwards, nor thought it remarkable when it was mentioned No ancient that wrote on astronomy would have missed the point There is also a photograph of the portrait in Magdalene College, Cambridge, which Edleston published, and a reproduction of the title page of the first edition, somewhat reduced laterally to make it fit

Tea and Tea Production

The Culture and Marketing of Tea By Dr C R Harler Pp xii + 389 + 8 plates (London Oxford University Press, 1933) 12s 6d net

DR HARLER informs us that "the first authentic account of tea was written by Lo-yu who lived about A D 780 He describes the preparation of the leaf, which, he says, must only be picked during certain moons and not when it is raining or the sky cloudy" that "China, the classic tea country, gave both the word 'tea' and the beverage to the world", and that "the words *te*, *chia* and *cha* denote tea in various Chinese dialects and in one or other of those forms has been transposed into most other languages" The first pound of tea imported into England is attributed to Lord Arlington in the year of the Great Plague of London (1665–66) It cost his lordship sixty shillings and was brought by him from Holland His residence, Arlington House (demolished in 1703), at that time was on the site where Buckingham Palace now stands (*see* "Old and New London", by Edward Walford, vol 4, p 62)

"Tea was known in Europe in the middle of the sixteenth century and the Dutch began importing it early in the seventeenth century. In Queen Anne's reign, tea drinking in England became fashionable and rapidly spread In 1703 the import into England was 100,000 lbs About a century later in 1805 it was 7½ million lbs Tea

was still then a 'China drink' and remained so for many years." Now, out of a world's production of about 900,000,000 lb the British Isles takes approximately half the amount Dr Harler (p 373) furnishes the interesting facts that "the annual tea consumption in Great Britain is about 9 lbs per head" and that "in Russia in normal times, the annual consumption per head in the towns is 3·7 lbs, in the villages 0 37 lb, in Siberia 1 8 lb and in Russian Central Asia and Turkestan 2 7 lbs"

A correspondent some time ago in the *Tea and Coffee Trade Journal* gave the British Isles as the largest consumer in Europe—9 87 lb per annum: at the same time quoting the figures for Germany, 0 20, Italy 0 009, France 0 09, and Holland 3 17 lb per head respectively

London is the most important market for tea, and it is practically the centre of the trade for all countries and, as with spices, so with tea the market is concentrated in Mincing Lane and immediate neighbourhood, where the stocks at any one time may lie between 100 or 200 million lb and upwards

At the present time it would seem that the tea trade, like certain other great agricultural industries, is suffering from over-production, and according to the work under review (p 382) "drastic steps were taken at the end of 1932 to reduce stocks", and an agreement was made between India, Ceylon and the Netherlands East Indies, which was calculated to put about 120 million lb of tea less on the market in 1933 The scheme is subject to modification from time to time for five years, and although the early effect on prices, it is considered, has been highly beneficial, the ultimate advantages would appear to be somewhat indefinite

In the preface, the author states that his book does not pretend to be an exhaustive treatise on tea, but records his experience during the fourteen years he had been connected with the tea industry in north-east India as a scientific worker in the service of the Indian Tea Association Nevertheless, the volume produced is serviceable and comprehensive On page 73 he records the facts that "when tea cultivation was introduced first into Java in 1825 and India in 1835, Chinese methods of preparation were employed The industry developed steadily in Assam and Northern Bengal and in these areas, collectively referred to with regard to tea as north-east India, hand methods were gradually replaced by machinery from 1870 onwards and distinct modifications in the Chinese process were introduced In Java and Ceylon the industry developed at a later date, and these countries have taken the methods of north-east India and adapted them to local conditions" Four chapters are devoted to north-east India, dealing with general aspects of the country, geology, climate, soils, etc, the development, culture and manufacture of tea, in the third part of the work. The whole subject is dealt with in four parts, the first giving a general description of the tea plant and tea production, the second on chemistry and pharmacology of tea, the third part—in addition to the four chapters—as above referred to, also includes chapters on tea in China and Japan, Formosa, Ceylon, Java and North and South India, and the fourth part, in two chapters, deals with the "British Tea Trade", the marketing, production and consumption of tea

There are eight good illustrations, and two maps—of north-east India, showing tea areas, and south-east Asia, including the tea districts of China and natural tea tracts

The useful modern works on tea are not numerous, and the author is to be congratulated on making an excellent addition to our store of knowledge on the subject J H H.

Science and Social Welfare

L'Économie humaine par la médecine sociale Par René Sand Pp vii+305 (Paris Les Éditions Rieder, 1934) 30 francs

IT would be difficult to over-praise this book, which ought to be promptly translated into the chief European languages. Nothing similar has yet been attempted, although, when done, one wonders why it has been left to Dr René Sand The reason no doubt is that he is a Frenchman, with the French gift for clear arrangement and for making the abstract attractive Within three hundred pages one has a perfect conspectus of what science, especially medical science, has done to raise the general health, and promote social welfare, within the last few decades Though the general conclusions are amazingly encouraging, there is no attempt to gloss over the black spots, which are described here and there with a poignant pen

The most useful is the earlier part of the book, in which is given a comparison which could scarcely be found elsewhere, of vital statistics with other conditions of life, sex, race, economic position and so on Two or three general conclusions stand out in startling uniformity One is, the universal agreement of better health with better economic conditions Another is the similarity of the movement in all countries, just in proportion to the degree in which they have organised their social services. The third, and most hopeful, is the steady increase in improvement in all the years under review—except, of course, in certain obvious cases due to the War. Even the two recent years,

which the author refers to as 'la crise', have not seriously abated the upward trend.

The knowledge shown of all the agencies at work, in what is usefully defined as 'la médecine sociale', is colossal Every author, every society and every movement in the civilised world comes under review and yet there is no crowding and no tedium The book is as easy and attractive to read as it is comprehensive and convincing It is, of course, what would in a loose sense be called 'socialistic', and towards the end the author adopts the 'ought' tone rather more frequently than is quite consistent with a strictly scientific point of view. One feels here and there that something might be said in defence of more individual liberty and in qualification of the all-embracing paternal rôle which is assigned to the State and the community. But this is no place to discuss a very large philosophic question Let us be thankful for the indisputable evidence of vital progress which the book affords, and hopeful for the continued benefits which science, whole-heartedly applied, holds forth in the future

F S MARVIN.

Short Notices

Collected Papers of Charles Sanders Peirce. Edited by Charles Hartshorne and Paul Weiss Vol. 3 *Exact Logic* Pp xiv + 433 24s 6d net Vol 4 *The Simplest Mathematics* Pp x + 601 25s net Vol 5 · *Pragmatism and Pragmaticism* Pp xii + 455 21s net. (Cambridge, Mass Harvard University Press, London Oxford University Press, 1933–1934)

IT is difficult to deal adequately, even in a longer notice, with the extraordinary diversity of topics touched upon or discussed in these volumes They fully support the editor's opinion that Peirce was "one of the most original and prolific logicians of the nineteenth century" Vol 3 contains mainly papers on the algebra of logic and the logic of relatives, in which several improvements on Boole's method are suggested There is also an excellent paper on the logic of number, and an essay on "The Regenerated Logic" which contains some pertinent remarks about the relations between mathematics, logic and philosophy For example, Peirce draws a distinction between logic and mathematics, to which he denies the character of a positive science in so far as it does not deal with any aspect of reality, while philosophy does deal with reality, if not through special observations, yet by the study of the universal phenomena of experience

Vol 4 deals with the various aspects of the logic of quantity and with the use and interpretation of existential graphs as aids to logical theory. The remarkable chapter on the "Simplest Mathematics" begins with an interesting discussion about the essence of mathematics and its main divisions. There Peirce defines mathematics as "the study of what is true of hypothetical states of things" (p 193).

Vol 5 is perhaps the most important one for the history of thought, in view of the fact that it contains practically everything of importance which Peirce is known to have written concerning his famous theory of "how to make ideas clear". Half this volume is composed of hitherto unpublished papers. Some of his most striking conclusions are that logic is subsidiary to ethics and æsthetics; that pragmatism is a method of logic rather than a principle of metaphysics, and that pragmatism entails scholastic realism which, in its final pragmatic interpretation, means the ascription of purposive habits to Nature These main theses are supported by a wealth of arguments covering the various aspects of the theory of knowledge A conscientious study of this volume would no doubt help the reader to discover a certain interpretation of pragmatism which is not generally current among the followers of this doctrine

Anatomy of Animal Types for Students of Zoology By Prof E A Briggs Pp xix + 250 (Sydney · Angus and Robertson, Ltd ; London Australian Book Co., 1934) 10s 6d net

PRACTICAL courses dealing with animals are a strong feature in the teaching of elementary zoology such as is required for medical students Many guides, dealing with suitable local animal types, have been published Most of these are dry-as-dust 'anatomies', the use of which is preceded by lectures These in the writer's student days dealt mainly with the forms of the different organs in a number of dead corpses, with notes on their evolution deduced from the same, whereas to-day the centre is the living animal in relation to its mode of life

Here for Australia, especially Sydney, is a little textbook for the practical work The animals chosen are Australian species, or cosmopolitan forms that have been introduced. Each is described as the student should examine it, proceeding from external features to internal anatomy, and suggestions are made as to drawings, dissections, microscopical examinations and so on. There are happily no illustrations in the book to distract the student's attention from the animal, the dissection of which is mainly of use in teaching observation and interpretation

The author's views are sound; he wishes to approach his animal from two points, "firstly, that of structure, and, secondly, that of function", but we fear he has largely forgotten the latter—and such simple examinations of function as might be possible —in his maze of anatomical fact His book is, nevertheless, an advance on most similar textbooks, but he should recast it on thoroughly modern lines so that Australian students may be freed from out-of-date manuals on practical zoology that are a curse not only to them but also render ineffective the best efforts of their teachers.

The Riddle of the Universe To-day By Joseph McCabe. Pp ix+250 (London Watts and Co, 1934) 5s. net.

THE author points out quite rightly that, in spite of some popular pronouncements about the idealistic or spiritual character of present day science, the materialistic interpretation of knowledge continues to flourish as it did in Victorian days A rapid survey of recent advances in every branch of science helps him to illustrate his contention, and to conclude that "neither physics nor mathematics could ever discover anything that would disturb the materialist You might as well hope to discover a spiritual world by the use of the spectroscope" (p 225) This is obvious if we restrict our knowledge artificially to the immediate data of the external world But this is not the sense in which should be interpreted the assertion that materialism has lost the predominant position it held some years ago This assertion simply means that the recent advances in the various sciences, coupled with the analysis of their possible interpretations, reveal in the world of inanimate things as well as in the mental and social life of the individual, a purpose, an order, a manifestation of causality which cannot be exclusively and ultimately accounted for in terms of matter However important, necessary and immediate matter is for the ordering of our knowledge, we are bound to admit its allegiance to a higher principle, that is, to spirit, with all its implications T G

Raumchemie der festen Stoffe Von Wilhelm Biltz. Pp x+338 (Leipzig Leopold Voss, 1934) 22 50 gold marks

PROF BILTZ is well known for his long series of researches on the physical chemistry of solids In this book, which brings together much previously published material and also many determinations which have not otherwise been published, he attempts a systematic survey of the whole field, the primary object being the determination of the absolute volumes of the ions in crystals. The first part of the book consists of a number of detailed tables, in which the rich experimental material is collected in an easily appreciated form, and in the second part a detailed discussion of this quantitative material is presented

Prof Biltz has had the assistance of other specialists, and the resulting volume is one which possesses an unusual interest not only for chemists but also for physicists who are concerned with crystals. Full references to the literature are given, and the collection of numerical data in the tables would in itself make the book very useful When this is accompanied by a systematic and detailed attempt towards the interpretation of the results, the value of the book is considerably enhanced. The relations with valency are particularly emphasised, and in this direction the monograph will appeal to both chemists and physicists The book is one which can be recommended as both rich in information and also in theoretical discussions which reach into many fields.

Hydrology and Ground Water: a Practical Text-Book for the use of Civil Engineers, Surveyors, Students, and all those who deal with the Control of Water By J M. Lacey Pp viii+159 (London. The Technical Press, Ltd, 1934) 10s. 6d

THIS is the re-issue of a textbook which was first published about eight years ago, and is based on a series of articles which originally appeared in the columns of *Engineering* It is a conveniently sized manual affording a good general survey of the subject in twelve chapters, which deal in turn with sources of water supply, measurement and variations of rainfall, evaporation, soil permeability, ground water and springs, run-off or surface yield, storage, floods and wells

Within its limits, the book provides quite a serviceable guide to those who have to deal with questions of water supply and control, but, as it professes to cater for the needs of "engineers who are engaged in Water Works, Irrigation, and Drainage schemes", it must be said that there are several respects in which the information supplied on those subjects is somewhat meagre Apart from floods, for example, land drainage receives no very conspicuous treatment If one were disposed to be captious, exception might be taken to the opening statement that "the source of all water ... is rain", ignoring the existence of snow, hail and dew as distinct forms of atmospheric moisture It is true that snow and hail are mentioned on the succeeding page, but only casually and without explanatory comment The formation of dew is left undescribed, and there is no mention of dewponds as a possible (though limited) source of supply The section on wells is perhaps the best, as it is the most extensive, constituting 40 per cent of the volume, with examples of calculation of yield, which assume a knowledge of the calculus on the part of the reader The author illustrates very largely from Indian practice

Indian Psychology Perception By Prof Jadunath Sinha Pp xvi+384 (London. Kegan Paul and Co, Ltd, 1934) 15s. net.

THIS very interesting work outlines and discusses the most important topics of Indian psychology with special reference to doctrines of perception. As there is scarcely any experimental psychology in India, introspection and observation are the basic methods displayed This fact, coupled with the synthetic and metaphysical characteristics of the Indian mind, points to the dependence of psychological doctrines on the fundamental currents of Indian philosophy Yet, observations and doctrines on specifically psychological questions are numerous and original enough to justify its special treatment Prof Sinha thus discusses the various aspects of Indian psychology in their proper setting Subtle analyses of mental processes are revealed both in normal and in abnormal psychology The three chapters on illusions, dreams and abnormal perception are very striking in this respect. Philosophers will welcome Prof Sinha's book as an important addition to their library.

A Condensation Theory of Meteoric Matter and its Cosmological Significance

By PROF. BERTIL LINDBLAD, Director of Stockholm Observatory

IN connexion with a theory on the constitution and development of stellar systems, I have recently directed attention[1] to the significance of the great difference in temperature between the interstellar gas and solid interstellar particles as an explanation of the origin and growth of meteoric particles. If we assume with Sir Arthur Eddington[2] a temperature of 10,000° for the interstellar gas and, on account of the low energy density, a temperature of about 3° for solid particles, the latter must be assumed to grow by the condensation of sublimed matter on their surface. This conclusion is in accordance with the conclusions drawn by I. Langmuir[3] concerning the nature of the process of condensation of metallic vapours on solids. In the present case, the energy of impact of atoms on the surface of the particle will be rapidly radiated into space, or perhaps to some small extent transformed into sub-atomic energy, so that the particle remains cold. We assume that the interstellar gas actually contains all the elements in about the proportions formed in the earth's crust and in the sun, and that the apparent predominance of calcium and sodium is due to the easy accessibility of very strong spectral lines due to these elements, namely, the *H* and *K* lines and the *D* line. For atomic weight 50, the temperature 10,000° gives a mean speed of the atoms of 2 km. per sec., and assuming a density of 5 for the solid particles formed, we readily obtain the formula

$$m = 10^{36}(\rho t)^3,$$

for the mass m of the particle in grams after the time t since the formation of an 'infinitesimal' nucleus expressed in years. For the density ρ of the interstellar gas we may adopt Gerasimovic and Struve's[4] value, 10^{-26} gm. per cm.^{3} In the time $t = 10^9$ years we then get particles of the size 10^{-15} gm., which is the order of magnitude of the particles in the obscuring clouds of the Milky Way according to the recent results derived by C. Schalén[5] from an investigation of the absorption effects in the photographic spectrum of early type stars in various Milky Way regions and an application of Mie's theory of the absorption of light by colloidal particles. It is remarkable that the mean density derived by Schalén from the number of particles per cubic centimetre agrees well with Gerasimovic and Struve's value for the interstellar gas. We may further remark here that the time of 10^9 years agrees with the average order of magnitude of the age of meteorites derived by an analysis of radioactive material.

The result obtained for the small interstellar particles encourages us to apply our formula to the formation of meteoric material in somewhat denser regions in space as well. Before leaving the small obscuring particles, we may add, however, that these particles will adopt motions corresponding to the mean motion of the interstellar gas, which we know follows closely the rotation of the stellar stratum around the centre of the stellar system situated in the direction of the constellation Sagittarius. (The distance to the centre is estimated to be 10,000 parsecs, or about 30,000 light-years. The period of rotation at the position of the sun in the system is nearly 2×10^8 years.) The consequence will be that the particles will get only small velocities relative to the circular motions, and will show a strong galactic concentration, presumably much stronger than the galactic concentration of the interstellar gas itself. This result is quite in accordance with the empirical data regarding the region of obscuration in our stellar system.

For an accumulation of material through gravitational forces to be possible in the case of an angular velocity of rotation corresponding to the period of revolution just mentioned, we should have a minimum density of about 10^{-22} gm. per cm.^{3} In 10^9 years we get with such a density particles of 10^{-3} gm., which seems to be the minimum mass of observed meteors. We assume here throughout a temperature of about 10,000° for the gas and a temperature near zero (absolute) in the case of the particles. Even rather large changes in the temperature of the gas, however, will not affect the order of magnitude of m.

If we assume the sun and the planetary system to have evolved from a gaseous nebula, stretching at a certain time over the orbits of Neptune and Pluto with a reasonable concentration towards the central nucleus, we might estimate the density in the outer regions of such a nebula to be something like 10^{-15} gm. per cm.^{3} We should then expect particles of 10^{18} gm., that is, one million million tons, to develop in 10^9 years. This is about the mass of one of the smallest asteroids. We do not suggest, however, that bodies of this size will go on condensing in this way undisturbed. We must expect particles of various size to combine occasionally to form still larger formations. On the other hand, especially in the denser regions near the central nucleus, the particles will run a great risk of being volatilised by violent encounters, and with increasing energy-density the temperature of particles will be too high to admit condensation

Further, inside Roche's limit around the centre no formation of large particles is possible Therefore there will probably be an optimum region for the formation of large bodies in the solar system, and we may assume this region to occur around the orbits of the giant planets Jupiter and Saturn We may mention here the well-known fact that the planet Jupiter contributes about 60 per cent of the total angular momentum of the solar system

The objection by H Jeffreys[6] to the 'planetesimal theory' of Chamberlain and Moulton that the planetesimals are likely to volatilise entirely before contributing essentially to the formation of larger bodies of small orbital eccentricities and inclinations does not apply generally in our case, since the condensed particles are likely to possess from the beginning only small velocities relative to the circular orbits in the plane of rotation of the nebulous mass In the extended solar nebula, viscosity will have produced at least roughly regular conditions, and because the pressure gradient is not likely to contribute much to support the gaseous matter against gravity, the mean motion of the gas, and hence the motion of the condensed particles, is likely to follow fairly closely the circular motion. I have further shown as a general theorem[7] that mild encounters leading to a dissipation of kinetic energy of the particles will, in the mean, lead to a concentration of the particles towards circular orbits in the plane of rotation. Still, owing to the large free surface per unit mass of the small particles, a very great number of these corpuscles will actually be evaporated by encounters, but some particles which succeed in growing without serious interruption will increase in size by accumulation of smaller particles at a rate probably exceeding considerably that of our condensation formula given above It appears, therefore, that the net result of the condensation process will ultimately be a rapid growth of a comparatively small number of large bodies We of course at once identify these bodies with the planets and their satellites

We may ask, incidentally, if there are in the universe types of objects which in any way resemble the primordial solar system as depicted above In actual fact, it is not unreasonable to assume that certain stars of early type with nebulous envelopes showing the reflected continuous spectra of the stars involved, which are not seldom observed in the Milky Way, constitute systems of a similar nature, that is, they consist of a stellar core inside a thin gaseous envelope which in the outer regions passes over into a meteoric cloud When, however, the central nucleus reaches a very high temperature, there must be a strong radiation pressure on particles of a certain size[8] In such a case we should expect not only an outgoing stream of small particles, for which radiation pressure increases with increasing size, but also an incoming stream of larger particles, for which the radiation pressure decreases with increasing diameter It is possible, further, that larger particles have formed at some time before the nucleus acquired by contraction a very high surface temperature Modern evidence[9] seems actually to indicate reflection by fairly large particles in the nebulous envelope We may assume that the types of objects in our stellar system which show the strongest galactic concentration have actually formed in the 'present phase' of the stellar system, that is, during the time in which the stellar system has possessed its present mass, angular momentum and invariable plane The minimum amount of time passed in this phase may perhaps be set down as 10^{10} years This seems to be near the upper limit of the age of the earth's crust If the sun, or rather the solar nebula, became differentiated out of the interstellar material in the present phase of the system, or during an earlier phase, seems therefore doubtful

Returning to the formation of the planets from the gaseous and meteoric material of the solar nebula, in accordance with the lines of thought just outlined, we assume that the earth has been formed around a heavy core by accumulation of a great number of particles of various sizes. In addition to the considerations dealt with earlier, we may direct attention to the circumstance that, between neighbouring particles formed by condensation of atoms of very large mean free path, and by accumulation of free particles of larger size, there will be a certain additional pull due to their shielding one another with respect to the free atoms or corpuscles falling in towards their surfaces As the accumulation may be thought to have been especially rapid at certain stages of the process, for example, in encounters with comparatively large bodies, the planet may ultimately have become heated to such an extent that at least the surface layers have been entirely in a fluid state, perhaps even incandescent A temperature of 2,000° of the radiating surface may be upheld, if material of a mean space density about 10^{-9} gm. per cm.^{3} falls in towards the radiating surface with a mean velocity of 10 km. per sec. At a later stage, through loss of heat by radiation, simultaneous solidification all over the surface has taken place

The formation of satellite systems is explained on general lines in a way analogous to the theory of formation of the planetary system itself. The fusion of particles of various sizes, leading to the formation of a massive planet, will in the first stage produce an incandescent nucleus with an extended gaseous atmosphere. The angular

momentum due to the satellite system and the rotation of the planet taken together correspond to the angular momentum of the matter which was sufficiently near a planetary nucleus to be retained in its neighbourhood by gravitation, or in the course of time has been caught in encounters. The direction of rotation should therefore be the *same* as that of the system as a whole, and thus that of the planetary orbits, the few exceptions to this rule are readily explained as accidental deviations due to local conditions (the Uranus system and the satellite of Neptune) or capture in recent times (Jupiter VIII and IX, Saturn IX). The strong correlation between the angular momentum of rotation of the planet and the mass of the satellite system is readily understood Apparently singular objects like the satellites of Mars may be understood without making the assumption that these bodies have originated directly out of the mass of the planet.

The rings of Saturn are perhaps best explained directly as small particles formed by condensation inside Roche's limit for the planet in question The extremely flat formation is explained partly by the condensation of the particles out of a gaseous cloud, which causes the particles to follow originally nearly circular motions with low inclinations, but mainly by the influence of mild collisions between neighbouring particles, as explained by Jeffreys[10] and on somewhat different lines by myself in a recent paper[11].

The corpuscles of the zodiacal light have possibly been formed fairly recently[12] out of the last remnants, perhaps reformed by volatilisation, of the nebulous cloud surrounding the sun

Finally we must mention the probable status of the meteorites. Their division into, roughly, two widely different kinds, stony and iron meteorites, suggests that they can scarcely be considered exclusively as direct condensation products We may perhaps get a general explanation of their physical nature, as well as of their motions, which obviously differ very much from the circular orbits in the invariable plane of the solar system, by assuming that they are, generally speaking, remnants of larger bodies, shattered by violent encounters in the manner which has been considered above Like the planets, these larger bodies have therefore formed to a great extent by accumulation of smaller particles We can then assume, in conformity with the views put forward by geophysicists[13], that a certain sedimentation of the various minerals has taken place at a fairly high temperature in the bodies in question before their disruption Those meteorites which did not originally belong to our system have probably emanated from analogous systems in other regions of the Milky Way, forming showers of particles traversing the voids of interstellar space much like the stars themselves In regard to their origin they are, according to our point of view, largely a sort of by-product in the process of formation of planetary systems

Deep Diving and Under-Water Rescue

SIR ROBERT DAVIS delivered the Thomas Gray Memorial Lectures for 1934 of the Royal Society of Arts, and spoke on deep diving and under-water rescue The lectures have now been published, they form a valuable study of the development of apparatus and technique, admirably illustrated and lightened by comments and anecdotes arising out of the author's lifelong experience of the subject

Divers have always wanted to get a little deeper, but the particular obstacle to be overcome has varied in successive generations. At first it was the matter of air supply, when the eighteenth century inventor and his victims "discovered by bitter experience that the leathern bellows, which worked so admirably when blowing an organ or smith's forge, were quite incapable of forcing air down to a diver" working at more than two or three feet deep Later, when the introduction of metal air pumps enabled a supply to be delivered at high pressure, came the mysterious, crippling, 'diver's palsy' which we now call compressed air illness Later still, when physiologists had elucidated the cause of this trouble and devised methods of slow decompression to avert it, came the economic difficulty that at depths of thirty fathoms and upwards, so much of the diver's time under water had to be used in decompression that only a fraction remained available for useful and paying work Now the invention of the Davis Submerged Decompression Chamber (see NATURE, August 29, 1931) has eased this situation and made salvage work in the rubber dress a practical procedure up to 300 feet depth; and there for the moment we rest.

The deep diver of to-day receives a measured supply of clean air from steam compressors An

injector circulates the air from his helmet through an absorbent which removes carbon dioxide as fast as his breathing produces it He is in constant telephonic communication with the organisation in the salvage ship above, which not only controls his decompression but also, through the agency of such devices as grabs and pneumatic tools, takes over an increasing share of the manual work to be done on the bottom Expensive plant, once started, should run continuously, hence a succession of fresh divers is required who have to subordinate their procedure to the common plan of the team The famous divers of the past, some of whose feats Sir Robert described, worked almost single-handed in far greater danger and discomfort, only the fittest mentally and physically could attempt the deeper work and these few acquired outstanding skill and experience It may be that we shall not see their like again

More than fifty years ago one of these men, Alexander Lambert, struggled through 1,000 feet of the wrecked and flooded Severn tunnel in complete darkness to close an iron door and enable the water to be pumped out As it was impossible to drag such a great length of air pipe behind him, he used H A Fleuss's newly invented self-contained diving-dress, putting it on for the first time that day This was the prototype of the now familiar type of breathing apparatus in which carbon dioxide is removed from the expired air by passing it over caustic alkali, and the oxygen consumed by the user is replaced from a high pressure cylinder This system is in use in mine rescue and fire brigade smoke helmet apparatus all over the world to-day, but has perhaps been carried to the highest point of development and portability in the compact Davis Submarine Escape Apparatus, which now provides each member of the crew of all British (and many foreign) submarines with the means of breathing in suffocating gases or under water until the escape hatches can be opened, when it will waft him gently to the surface and support him there until help arrives

The Future of Tropical Australia

By Dr L Dudley Stamp

FOR more than a century the British Government, the colony of South Australia, and the Australian Commonwealth have attempted to develop the half million square miles contained within the Northern Territory More than £17,000,000 has been expended in the effort, yet to-day the entire population consists of some 3,000 whites, 800 yellow persons, 900 half-castes and probably 20,000 aboriginals The mining and cattle industries, once promising, have declined. The same state of affairs is found in the tropical parts of Western Australia, where the total non-aboriginal population is less than 2,000 It is only on the patches of richer soil along the coast of Queensland that the population of tropical Australia is relatively flourishing and increasing.

A few years ago, Prof Griffith Taylor[1] was almost alone in declaring that only three per cent of tropical Australia—entirely in the coastal belt of Queensland with its well-distributed rainfall—was suitable for tropical agriculture and consequent close settlement His views are gradually becoming generally accepted, but there is still a wide divergence of opinion on the reasons for the lack of settlement Sir James Barrett in a recent article[2] says, "It is generally assumed that there is a medical, or rather physiological, reason for failure to settle parts of tropical Australia So far as investigation goes there is nothing of the kind. The failure to settle some parts of tropical Australia and the successful settlement of other portions of the tropics is solely economic" In his consideration, he rightly divides tropical Australia into four regions (1) the coastal districts of Queensland with good soil and abundant rainfall, (2) the western portion of Queensland suitable for grazing, (3) the Northern Territory and (4) the northern portion of Western Australia similar in character to (3) He shows that in the last ten years the annual increase of population in tropical Queensland has been 2 per cent per annum, against 1·5 per cent for non-tropical Australia He finds that birthrate, infantile and general death rates in tropical Queensland compare favourably with those of many non-tropical countries, are better than those of metropolitan non-tropical Australia and are little if at all inferior to those of Australia as a whole

It is, as Sir James argues, unfair to consider the vital statistics for regions (3) and (4) because of the small size of the sample Economic nationalism and State socialism are blamed for preventing more rapid development of tropical Australia—"it is certain that it is not the effect of the climate on Anglo-Saxons" On the other hand, R. W. Cilento, director of Australian tropical hygiene, considers that the Commonwealth is evolving a new type of person—the North Queenslander—who "moves slowly and conserves his muscular heat-producing energy in every possible way"[3], thus agreeing with results of experiments carried out by American physiologists recently[4]. The

vital statistics quoted by Sir James Barrett prove the efficient work of the medical services rather than the absence of climatic influence on life and habits

In a thoughtful and well-documented study[5], A Grenfell Price, of the University of Adelaide, has reviewed the attempts to settle and establish agricultural or other industries in the Northern Territory The thorough work of this geographer has been recognised by the award to him of the Commandership of the Order of St Michael and St George and the doctorate of the University of Adelaide in 1933 He has summarised his views on the major problem in a paper entitled "Pioneer Reactions to a Poor Tropical Environment"[6], and concludes that "there is little hope for anything more than a sparse pastoral population in the greater part of the Australian tropics and that this population will show strong reactions to a poor and difficult tropical environment There is, however, some possibility that Australians *may* permanently establish close settlement by white agriculturists in small and favourable areas, particularly on the east coast of Queensland"

Dr Isaiah Bowman[7] suggests that, so far as the Northern Territory is concerned, it would be better to "give up this painful experiment on an incorrigible frontier and let the land revert to wilderness"

If the land has now been properly assessed, the real danger of 'an empty north' to the 'White Australia' policy disappears Sir James Barrett points out the accessibility of the Northern Territory from densely peopled areas, such as Java, and argues that had conditions been suitable it would long ago have been colonised by Malays or Javanese On the other hand, there was not, perhaps, sufficient economic pressure to necessitate the inhabitants of the East Indies seeking settlement in lands less attractive The position to-day is somewhat different There is a close correlation between climatic and soil conditions in the region around Darwin and in some of the poorer parts of peninsular India Will the future alter the value of tropical Australia in the eyes of overcrowded India ? Darwin is clearly destined to remain on a major world aerial route, and in this connexion at least the Northern Territory cannot remain entirely empty

Obituary

SIR ALFRED EWING, K.C.B., F.R.S.

JAMES ALFRED EWING, like many Scots who have become distinguished in the fields of literature and science, was a son of the manse He was born on March 27, 1855, in Dundee, where his father was a minister of what was then called the 'Free Church of Scotland', his father having 'come out' in the Disruption of 1843 In the autobiographical section of "An Engineer's Outlook", Sir Alfred described his father as a man who, with a superb physique, never missed a day's duty through illness, or shirked one for any reason, the same words might be applied to Sir Alfred himself He seems to have owed much of his early education to his mother As he so happily phrased it, "She gave us much of what other boys got at school, and did it in a way that made us associate a love of learning with our love of her".

From Dundee High School, Ewing proceeded in the early '70's to the University of Edinburgh, the first holder of an engineering scholarship in the gift of Dundee High School, and his career as a student was prophetic of the distinction he was to acquire in later life—the records of the Engineering Department show that during the session 1871–72 the prizeman in the class of engineering was James Alfred Ewing. It was his good fortune to be a student during the time when Tait and Fleeming Jenkin were at the zenith of their powers, and undoubtedly Ewing owed much of his zest for research to the inspiring influence of these two teachers Through Jenkin he was brought into contact with Sir William Thomson (afterwards Lord Kelvin), and he took an active share in the early development of submarine telegraph cables, making in connexion with this work three cable-laying voyages to Brazil and the River Plate

In 1878, on the nomination of Fleeming Jenkin, Ewing went to Japan as professor of mechanical engineering in the University of Tokyo, and there spent what he termed "five educative years". In the latter part of this service one of his duties was to undertake teaching in physics, and he there began his classical experiments on magnetism

It was while in Tokyo that Ewing married his first wife, Miss Washington, a great-great-grand-niece of the first president of the American Republic He had two children, born in Japan, by his first wife, who reached mature years before their mother's death In 1911, shortly before he was appointed to the principalship of the University of Edinburgh, he married as his second wife a daughter of the late Prof John Hopkinson, a past-president of the Institution of Electrical Engineers, by whom he had a son.

After five years service in Japan, Ewing decided

to return home, although the Japanese authorities were anxious to retain his services for another two years He had been offered, however, the professorship of engineering in University College, Dundee, and there he had seven years of further experience in teaching and research

In 1890 Ewing was appointed to the chair of mechanism and applied mechanics in the University of Cambridge as successor to James Stuart. The last years of Stuart's occupancy of the chair had not been happy ones, as his attention had been largely diverted from engineering to politics and journalism, and the University was disinclined to continue the engineering department, if that were possible, fortunately, a wiser decision was taken By the generosity of donors, Ewing soon acquired a laboratory, where research work could be carried on and ordinary laboratory instruction given The school flourished, the number of students increased rapidly, and, in 1899, a generous gift in memory of Prof John Hopkinson from his widow and children provided the funds for a much needed enlargement of the laboratory buildings By 1903, when Ewing severed his connexion with the University of Cambridge, the Engineering School was one of the largest in the country, and its output of research testified to Ewing's great influence upon those working with him

In 1903, the Admiralty was about to introduce what was known as the New Scheme of Naval Education After an interview with Lord Selborne and Sir John Fisher, Ewing was offered the post of Director of Naval Education on very generous terms This opened up for him an entirely new sphere of work It meant that he had for the time being to abandon his researches and to drop his professional practice That this new scheme became a complete success was largely due to Ewing's extraordinary gift for administrative work, as there was opposition to some of the changes which had to be introduced

When the War broke out in 1914, Ewing was still Director of Naval Education, but almost at once he was asked to undertake an entirely new and onerous duty, namely, the problem of dealing with enemy cipher This led to the creation of a department which came to be known as "Room 40". The work carried out in Room 40 was strictly secret, and no section of our defence work was more unknown to the general public and to the enemy The secrets of Room 40 have never been divulged, though Ewing himself removed the veil slightly in a lecture he gave before the Edinburgh Philosophical Institution in 1927 Prior to this, the late Lord Balfour, then Chancellor of the University of Edinburgh, disclosed the fact that Ewing had been the head of the organisation in Room 40

It was while carrying on this work that Ewing was invited in 1916 to fill the dual office of principal and vice-chancellor of the University of Edinburgh. He was somewhat averse to undertaking this fresh burden, but was persuaded by the late Lord Balfour to accept office, while still continuing his work at Room 40, and it was not until May 1917, when he handed over the control to Admiral Sir Reginald Hall, that he was able to devote himself unreservedly to his University duties.

When he accepted office at Edinburgh, Ewing was sixty-two years of age, and it is a striking testimony to his extraordinary capacity for work and to his bodily vigour that, starting at that late age in an entirely new sphere of work, he was able in the twelve years of his principalship to accomplish such great and far-reaching changes in the development of the various departments of University life He realised that the War had brought many new problems in education and industry, and that the great universities would have to play a very important part in the necessary solving of these problems. Rapid developments in specialised study made it essential to found new chairs and lectureships, and during his term of office at Edinburgh no less than thirteen new chairs were established—six in the Faculty of Arts, four in the Faculty of Medicine, and three in the Faculty of Science—besides a number of lectureships in new subjects or in some of the older subjects where the teaching had to be extended A new degree in commerce was established, and the degree of Ph D was instituted in the hope of encouraging post graduate work and research The increase in the number of the teaching staff involved as a corollary an extensive scheme of new buildings It was impossible to find a site for the necessary new buildings in the immediate vicinity of the Old College, and Ewing decided to recommend the purchase of a large area of ground about a mile and a half south of the Old College, where during his principalship independent blocks were erected for chemistry, zoology and animal genetics, while plans were prepared and finances provided for new blocks for geology and engineering, built, however, after he had retired These blocks of buildings, known as King's Buildings, will remain as a permanent memorial to Ewing's term of office as principal of the University of Edinburgh

Needless to say, such an extensive increase in the number of teaching staff and the erection of these buildings involved very heavy expenditure Fortunately, Sir Alfred had a very persuasive tongue, and he was able to secure handsome gifts from private benefactors and public trusts, running into a total of more than three-quarters of a million sterling, and was thus able to carry through his improvement schemes without laying any serious burden upon general University finances.

During his twelve years of office, crowded as they were with administrative and social duties, Ewing was still able to find time to carry on research work, which had been his chief pleasure and object in life. He was an active member of many of the special committees of the Department of Scientific and Industrial Research, being chairman of the Bridge Stress Research Committee, which issued a valuable report in 1928 The necessary experiments on railway bridges throughout the country had to be carried out usually during week-ends, week-ends which an ordinary man at Ewing's age would have given over to rest and recreation, especially after he had

spent the previous five days in strenuous University work He was also chairman of the Timber Mechanics Committee, and so recently as July 1934 that Committee issued a report, largely the work of Ewing himself. There can be little doubt that Ewing habitually overworked himself during the last three or four years of his life—work was his passion, especially research work, and it was to research work that he devoted his main energies during his last years

It is interesting to remember that, as Ewing began his university career and his life's work more than sixty years ago in the engineering class-room of the University of Edinburgh, so he made his last public appearance in the lecture room of the engineering department only last October, when he delivered an address entitled "For Better or Worse" to the members of the Associated Science Societies of the University How much he was beloved by the students of the University was attested by the fact that he was known to them by the affectionate nick-name of "Alfy", and, at the conclusion of his last address, after the formal vote of thanks had been proposed and carried, the student audience rose to its feet and gave, as only students can, three rousing cheers for "Alfy".

Ewing's last years were largely occupied by the thought that man's ethical development had not kept pace with the advance of science, that science and engineering had placed in the hands of mankind tools which man had not yet learned to use wisely This formed the main theme of his remarkable presidential address to the British Association for the Advancement of Science at York in 1932 In "An Engineer's Outlook", published two years ago, one of the reprinted lectures was the Hibbert Lecture, delivered at the University of Cambridge in February 1933, on "Science and some Modern Problems" This lecture summed up Ewing's creed, after sixty years of active life in the service of education and science, he could find no better principle to urge on his listeners than the old gospel of goodwill—"*Thou* shalt love thy neighbour"—this, he said, is not a mere general injunction, it is an individual message

Ewing was the recipient of many honours. He held honorary degrees of the Universities of Oxford, Cambridge, Durham and St. Andrews He was elected a fellow of the Royal Society in 1887, and in 1895 received a Royal Medal for his researches on magnetism. He was elected an honorary member of the Institution of Civil Engineers in 1929, and of the Institution of Mechanical Engineers in 1932. He was made a Companion of the Bath in 1907, and Knight Commander of the same order in 1911. He was the author of many papers on scientific subjects, published in the *Transactions of the Royal Society* and other scientific societies His textbooks include "Magnetic Induction in Iron and Other Metals"; "The Steam Engine and Other Heat Engines", of which many editions have been issued, and which has been translated into many languages; "The Mechanical Production of Cold", "Thermodynamics for Engineers" and "The Strength of Materials".

T. HUDSON BEARE.

Sir Alfred Ewing and his Cambridge Chair

The Jacksonian professorship of natural and experimental philosophy at Cambridge is an old foundation dating from 1783 It was the duty of the professor to give experimental lectures on "Natural Experimental Philosophy and Chymistry", and the chair had been held by a succession of distinguished men In 1875 it was vacant through the death of Prof Willis, who had been its occupant for nearly forty years His predecessors had been chemists

By 1875 it was recognised that the study of the natural sciences deserved fuller encouragement Maxwell, a few years previously, had been appointed to the chair of physics Foster was lecturing as a Trinity prælector, Frank Balfour was beginning his work on comparative anatomy, and Liveing was teaching chemistry to an ever increasing number of students It was clear that he needed help, the Jacksonian professorship again became a chemical chair and Dewar was invited to fill it

At the same time, it was felt that mechanism and applied mechanics should still have a place in the University course, there was a man in Cambridge who could carry on some part at least of Willis's work, and so a professorship of mechanism and applied mechanics, to "terminate with the tenure of office of the professor first elected" unless the University should determine otherwise, was established, and James Stuart became professor There were some, Coutts Trotter for example, who, even then, sixty years ago, realised that the scientific study of engineering was a fitting subject for inclusion in the scheme of an ancient university It was a long step from this appointment to a professorship of engineering It was to be the duty of the professor to lecture on the principles of mechanism, the theory of structures, the theory of machines including the steam engine and other prime movers

There was an ordinary degree in mechanism and applied science, for which students were advised to read parts of Weale's Rudimentary Series, Balfour Stewart's "Heat", Bird and Brooke's "Elements of Natural Philosophy", and Ganot's "Physics". There was no laboratory, no provision for experimental work. But the professor started his work He raised funds for a certain amount of apparatus, some tools and workshop appliances, which ultimately were taken over by the University. A shed was erected to hold these, and by slow degrees the work grew

Some ten years later (1886–87), there was much controversy as to the place workshops should hold in a scheme for an honours degree in engineering then under discussion. A syndicate appointed to investigate among other things the "whole question of the workshops" was granted, in 1890, "further powers to enquire whether it be desirable to develop further the Engineering School in the University on the lines suggested" in a memorandum it had issued, and as a result, on November 10, 1892, the Mechanical Sciences Tripos was established The Tripos was to be in two parts covering the usual subjects of examination for an honours degree in engineering, together

with—an addition of 1895—a paper of essays having "reference to the fundamental principles, history, philosophy or applications of the Mechanical Sciences"

Meanwhile, Prof Stuart had resigned and, to quote the "University Calendar", in "1890 J. A Ewing, B Sc Edinb" had been appointed professor He came, personally unknown to us, but with a distinguished career as a teacher at Tokyo and Dundee, a pupil of Lord Kelvin, the author of papers on magnetism of outstanding merit In 1881 he had described the effects which follow the application of a cyclical process of magnetisation to iron and other material, that tendency of the magnetisation to lag behind the application of the magnetising force, to which he gave the name of *hysteresis*, and in 1885 had contributed a striking paper to the Royal Society entitled "Experimental Researches in Magnetism"

Ewing established himself at once as a *persona grata* to the University, a colleague, soon to be our leader, whom some of us who had been active in urging that engineering should receive full recognition from the University welcomed whole heartedly among our ranks To his wise judgment and sane advice are due the general acceptance of the scheme of education proposed The debt due to him by the University may perhaps be measured by the success of that scheme which, aided by his staff, Peace and Dalby and Lamb, he developed for the next thirteen years

A committee was set up in Cambridge to obtain funds for the establishment of an adequate laboratory for the teaching of engineering in the University Sir J J Thomson, Prof Newall, Sir Napier Shaw and myself are the sole survivors Ewing was the treasurer We had the help of a large and distinguished general committee which contained the names of all the great engineers of the day We stated that £20,000 would be required for the complete design, but that much could be done for £4,000 or £5,000, and with the money so raised the Engineering Laboratory made its start What it has now become engineers are well aware

The first Tripos examination was held in 1896, Ewing, Osborne Reynolds, and Shaw were the examiners, seven candidates passed, of whom three were placed in the first class Now the Engineering Tripos list is among the largest in the University

Since those days, Sir Alfred has done more great work for his country In Cambridge he will ever be remembered as the founder of the Engineering School, the man who taught the University what science, so long at home there, might do for industry and how that task might be achieved

R T GLAZEBROOK

Sir Alfred Ewing and Naval Education

THE connexion of Sir Alfred Ewing with naval education came about through the decision of the Admiralty, in 1902, to carry out a root and branch reform of the training of officers and men in all sections of the Navy The reform was long overdue, for even up to 1901, junior officers spent a part of their time in learning to manœuvre ships under sail, although for all practical purposes sails in warships had been obsolete for thirty years Then, too, there was the urgent problem of the staffing of the engine rooms of the steadily increasing fleet, a problem rendered difficult by the failure of successive Boards of Admiralty to adjust the status of naval engineers in accordance with their responsibilities.

Though at the beginning of the century, naval training was discussed in many quarters, the credit for the re-organisation of naval education in 1903 to meet modern requirements belongs in the first place to Lord Fisher (then Admiral Sir John Fisher), who had recently become First Sea Lord The first step in the reform was the publication in December 1902, over the signature of Lord Selborne, of the famous "Memorandum dealing with the Entry, Training and Employment of Officers and Men of the Royal Navy and of the Royal Marines" That memorandum stated that "In the old days it sufficed if a naval officer were a seaman, now he must be a seaman, a gunner, a soldier, an engineer, and a man of science as well", and that "the three branches of the Service which are essential to the fighting efficiency of the Fleet—the Executive, the Engineer and the Marine" were to be recruited by one system and all officers were to be trained alike up to a certain age

These were ideas entirely new to the Service and to carry them into effect it was obvious that the Admiralty would require a man of outstanding reputation Their choice fell on Sir Alfred Ewing, who in the preface to his book, "An Engineer's Outlook", tells of his first visit to the Admiralty, when he met Lord Fisher, "that volcanic personality whom, later, I was to see often in quiescence and in eruption, and to learn something of his greatness". This visit led to Lord Selborne offering Sir Alfred the appointment of Director of Naval Education.

To a civilian, the task Sir Alfred undertook might well have appeared a complex one, for in the course of a few months he found himself responsible for the training given in the Royal Naval College, Greenwich, H M S *Britannia*, the new Royal Naval College at Osborne, the Royal Naval Engineering College at Keyham, the Dockyard Schools at Portsmouth, Chatham and Devonport, various training establishments for seamen, stokers and artificers, together with the supervision of the work of some eighty naval instructors of university standing, many of whom were serving on distant stations. The Selborne-Fisher scheme naturally cut across many traditions and found not a few critics, while from the members of the Board of Admiralty Sir Alfred received every assistance, among those below them he was sometimes conscious of cross-currents

From the beginning it was realised that the new system of training would have to be modified in the light of experience, and many changes have been made It may, however, safely be said that naval education to-day owes more to the work done by Sir Alfred Ewing between 1903 and the War than to any other single individual.

News and Views

Mr. Lloyd George's Plans for National Development

MR LLOYD GEORGE, outlining at Bangor on January 17 his proposals for national development, said that the supreme paradox of our generation is that millions of people are living in poverty and despair, not because of scarcity but because of over-abundance Foremost among the problems of to-day and to-morrow is the question of securing peace among the nations, since whatever economic and social system is built up, unless it is based on peace, it will be founded on a quicksand. Next there are the obstacles to world trade, commerce and shipping which have multiplied enormously in the last few years We are to-day confronted with a twofold problem, first of temporary unemployment due to abnormal conditions, and secondly of permanent unemployment which cannot be absorbed under the existing system Our aim should be to find work for the workless instead of providing doles, and where private enterprise has been proved to be palpably unable during the present emergency to solve our national difficulties, the administrative and financial resources of the nation as a whole should be made responsible for setting on foot and supporting those developments in town and country which would bring our unutilised labour, our idle capital and our undeveloped resources into fruitful activity. Something on these lines has been attempted here and there—in housing, roads and other public works—but where it has been done, it has been done sporadically and inadequately

MR LLOYD GEORGE's main proposal is that a permanent body should be set up for the purpose of thinking out and preparing schemes of reconstruction which would provide useful and necessary work The functions of this Development Council would be to take a survey of the industrial, agricultural and financial resources and potentialities of Great Britain, to prepare and approve plans for industrial organisation, land development and the like, and to concede the application of the national credit with the view of properly financing the programmes it decides to carry out. Its duties would include the putting forward of recommendations to enable any important branch of industry, such as coal, cotton, iron and steel, shipping or agriculture, to re-organise itself, where the authority and the financial credit of the State may be needed to ensure proper measures being taken Further scope for its activities would be found in meeting the lamentable deficiency of decent houses, in road improvements, in the development of rail ways and canals, in the development of telephones, electricity and water supply and in land settlement. Mr Lloyd George also advocates a fundamental change in the constitution of the Cabinet In an emergency like this, the Cabinet should consist of a small body—not more than five—of the ablest men available and not of about twenty men immersed in the detailed administration of gigantic departments of State.

General G. Ferrié (1868–1932)

THIS great and singularly attractive man died so long ago as February 16, 1932, but we did not succeed in obtaining an obituary notice of him Many of our readers who knew him or his work will therefore be interested to learn of a series of eulogies and accounts of his life (*Bulletin de la Société d'Encouragement pour l'Industrie Nationale*, 133, Oct 1934, pp 533–564) They include a funeral oration broadcast from Paris on the day of his death by Lieut-Col P Brenot, a discourse given at his funeral two days later by M R Bourgeois, president of the Paris Academy of Sciences, a lecture on March 10, 1932, to an association of Engineers' regiments, by Lieut-Col P Brenot; discourses by General Perrier and M Painlevé (then Air Minister) at the inauguration of the plaques bearing the title of the newly-named Avenue du Général-Ferrié, at the Champ du Mars, October 10, 1932, a discourse of November 15, 1933, by M Emile Picard, at the inauguration of a monument to General Ferrié, near the radio-telegraphic station at the Champ du Mars; a discourse by M René Mesny, November 17, 1933, at the Academy of the Marine, and discourses by MM J. Paraf and de Valbreuze, at the inauguration of a memorial medallion at l'École supérieure d'Électricité, Malakoff (Seine), where General Ferrié for many years gave and directed instruction in radio-telegraphy

BORN in Savoy in 1868, Ferrié entered l'École Polytechnique in 1887 and was sub-lieutenant in the 'Engineers' in 1889, specialising in telegraphy in 1893 His introduction to radio-telegraphy came in 1898, when he studied the Hertzian waves after the publication of Marconi's first experiments In 1899 he assisted in Marconi's famous experiments in radio-communication between Folkestone and Boulogne, and shortly afterwards was appointed by the Minister of War to develop the military applications of this new mode of communication For many years he carried out this task with very little material or financial support, and battled magnificently against official inertia and incredulity Gradually his ability, his faith, his energy, his initiative, his organising power, his devotion, led to successes which gained for him growing recognition and support. He built up a military radio organisation, first tested in the Morocco campaign of 1908, in which he took part, and enormously and most effectively expanded during the War of 1914–18. In 1903 Ferrié instituted the radio station at the Eiffel Tower, whence, later, in conjunction with the Paris Observatory, he transmitted the time signals which have played so important a part in subsequent progress in time and longitude determination. After the War, Ferrié took a most honoured place in international scientific work, being president of the International Commission of Longitudes by Radio-Telegraphy, and of the International Union for Scientific Radio-

Telegraphy. He was honoured in very numerous ways by scientific bodies in France and in other countries. In 1930, by a special law, he was made General for life, a signal testimony to the place he had attained in the esteem of his country Not only was he respected and admired for his ability and power, but also all who knew him loved him for his courtesy and his goodness of heart

Bequest for Bacteriology at Edinburgh

MRS CAMERON, widow of Lieut Col Lewis Cameron, Indian Medical Service, who died at St Helier, Jersey, in 1930, bequeathed all her estate and effects to the University of Edinburgh and directed that the fund, to be known as 'The Lewis Cameron Fund', should be utilised in establishing a yearly prize f the best paper on bacteriology or on the diagnosis of disease by students of the University The estate amounted to £103,771 This amount was regarded by the University as out of proportion to the purpose of the bequest The University gave an undertaking to Mrs Cameron's executors that they would make application to the Court of Session for a scheme for the regulation of the purposes affecting the estate, and on January 14 the Court approved the administration of the fund as follows £3,000 for the establishment of two yearly 'Lewis Cameron' prizes of £50 each, one open to undergraduate students and the other to post-graduate students of the University for the best papers on subjects related to bacteriology or to the diagnosis of diseases, £15,000 for the endowment of a 'Lewis Cameron' teaching fellowship in bacteriology, £15,000 to stabilise by endowment one of the existing lectureships in bacteriology, £10,000 to form a 'Lewis Cameron' research fund, and £10,000 for a 'Lewis Cameron' library fund to provide books relating to bacteriology and the diagnosis of disease The remainder of the estate, about £50,000, is to be set aside as the nucleus of a building fund for providing additional accommodation and equipment in the University for teaching of the sciences bearing on the diagnosis of disease and for research in those sciences. It is hoped that allocation of this sum for buildings may enable the University to obtain assistance from other sources, and so make possible an extension of the medical buildings and of their equipment necessary to maintain the reputation of the University as a centre of medical education and research.

Exhibition of Primitive and Chinese Art

Two exhibitions of objects of art are being arranged for this year, which will be of no little scientific, as well as æsthetic, interest Of these, the first will illustrate the art of primitive peoples. This exhibition will take place in May next and will be held under the auspices of the Burlington Fine Arts Club. Although the various schools of primitive art, if that term may be used, are well, and on the whole fully, represented in the national and public collections, examples must as a rule be subordinated to the general scheme of museum arrangement, and other material distracts from their proper appreciation If, as no doubt will be the case, representative series are shown, their close association within the compass of a single exhibition should lead, by force of comparison and contrast, to an extended perception among the general public of the variety of primitive art in ideals, technique and achievement, as well as to a clearer understanding of the part played by artistic products in relation to the life and mentality of the peoples who have produced them On the other hand, it may be anticipated that the primitive will not be without effect on the more sophisticated culture The influence of African art in wood and ivory carving on the development of modern schools of art in painting and sculpture early in the present century will serve as a reminder that primitive art is not without something more than antiquarian interest in the theory of æsthetic.

THE second exhibition is of an entirely different character and will be the product of international co-operation on an extended scale The Royal Academy has arranged to hold an exhibition of Chinese art from November 1935 until March 1936 The King and Queen and the President of the Chinese Republic will be patrons, and the exhibition will be held under the auspices of the British and Chinese Governments As it is intended that the exhibition should illustrate fully the art and culture of the Chinese from early times down to 1800, a unique opportunity will be afforded for placing China in something like true perspective in the history of world civilisation The art of China, as is well known, played no inconsiderable part in the development of the art and culture of Western Europe from the eighteenth century onward, but this was only at a late phase in a remarkably long line of development In this exhibition the association of 'classical' with the products of early and prehistoric culture, especially in the instance of the last-named of the more recently discovered, to which additions are being made continuously, will serve as a much-needed corrective of some popular misconceptions of the standing and achievement of the Chinese as a people It may possibly also serve the useful purpose of stimulating a more active interest in their own antiquities among the Chinese themselves An influential organising committee has been appointed with Lord Lytton as chairman, and Mr Laurence Binyon, Mr R L Hobson, Sir Neil Malcolm, M Paul Pelliot and Prof Perceval Yetts among its members. This committee will co-operate with a local Chinese committee of State officials under the presidency of the Minister for Education in the selection of exhibits from China Other exhibits will be drawn from collections in Japan, Europe and America.

History of Dyestuffs in Great Britain

MR C T. J. CRONSHAW, director of the Dyestuffs Section of Imperial Chemical Industries, Ltd, is this year's Jubilee Memorial lecturer for the Society of Chemical Industry, and he spoke under the title "In Quest of Colour" before a joint meeting of that society with the Institute of Chemistry in Newcastle

on January 15 This proved to be a comprehensive account of the history of the dyestuffs industry in Great Britain, and traced the development and expansion of the chemist's skill and the dyer's needs since Sir W. H. Perkin's original discovery in 1856 Perhaps the most interesting section of the address was the examination of the causes which produced the rise, and then, in England, the decline of the new manufacture In the first place, the time was ripe for such a discovery because the successful application of machinery to the textile industries and the increase in available wool (from Australia) offered almost unlimited expansion, and also as England was a wealthy country and the workshop of the world As for the decline, Perkin himself attributed it to three causes the Patent laws, the ease of infringement abroad, and foreign import duties Others have blamed the textile manufacturers and the greater facilities for scientific publication in Germany at that time, but Mr Cronshaw placed above these, lack of foresight, and the fact that the leaders of the industry retired too soon Perkin was certainly the leading technologist of his day, and he retired at the age of thirty-six years, Caro at thirty-five in 1869, and Nicholson in 1868 Perhaps the early success was too easy, and proved to be dearly bought

Queen Maud Ranges of Antarctica

THE American expedition to the Bay of Whales in the Ross Sea is reported by *The Times* to have undertaken a most successful dog-sledge expedition to the Queen Maud Ranges, which amplifies the work of Dr L M Gould of the previous Byrd expedition of 1929–30 A party of three under Mr Q A Blackburn reached the Thorne glacier, which lies in about lat 86° S, long 153° W, and then ascending the glacier reached the surface of the polar plateau at an elevation of about seven thousand feet The ranges appear to continue with decreasing heights to the north of east This direction may lead to Coats Land in the Weddell Sea or possibly towards Hearst Land At the top of the glacier, deposits of coal are reported to have been found This would appear to be the same deposit found on the Beardmore glacier and the carbonaceous layer found in the flank of Mount Nansen. There is thus a confirmation of the suggestion made some years ago by Sir Edgeworth David of a great coalfield associated with the Beacon sandstone of the polar plateau The brief cabled report also refers to a subplateau at an elevation of 2,500 ft between the Ross Sea ice and the level of the polar plateau This was called the Leverett glacier in 1929 The sledge party reached three degrees from the Pole before turning back, and altogether covered 1,410 miles in 88 days

Effect of Rough Seas on Marine Structures

ON February 2–3, 1934, a storm of exceptional severity was experienced along the northern coast of Africa and led to the destruction of more than 1,300 ft. of the recently constructed Mustapha Breakwater at Algiers. The storm and the damage done is described by Dr. B. Cunningham in *Engineering* of January 11 There are several moles protecting the Port of Algiers, but whereas the older ones are rubble mounds, the Mustapha Breakwater consisted of a vertical wall 11 m thick with its base resting on a rubble foundation 50 ft below mean sea-level It was recognised as one of the finest examples of its kind The wall successfully withstood a severe storm on December 31, 1933, when it was subject to waves 6–6½ m in height and 100 120 m in length, but was completely destroyed by the storm of February 2–3, 1934 Observations made during this storm showed that the wall was being subject to the action of waves 9 m in height, 200 m long and with a period of 13½ seconds, and photographs taken shew unbroken masses of water 2 6 m thick passing over it There were three stages in its destruction (1) erosion of the bed of the sea in front of the rubble foundation, (2) the sudden removal of the rubble foundation by one or more great waves, and (3) the excavation by the sea of a trench into which the wall collapsed It has been generally thought, says Dr Cunningham, that a level of about 40 ft below the sea-surface marked the limit of appreciable dislocation of rubble foundation mounds by wave action, but this view now needs reconsideration, and it is clear that the effective suction of a back draught following wave stroke may extend to depths far below the accepted standard Fortunately, the failure of the mole did not lead to damage to shipping in the harbour It has now been decided to replace the wall at once with a breakwater of the classic mound type.

Removal of Smoke and Acid Constituents from Flue Gases

PRACTICAL remedies for preventing or reducing the emission of objectionable constituents in flue gases have in the past been mainly confined to the elimination of grit and dust emission In large urban areas it is now realised that the acid emission is attended with more serious consequences In 1927, Parliamentary sanction was only given to the erection of Battersea Power Station on the condition that the best practicable means should be taken to remove the oxides of sulphur from the flue gases In a paper on a new method of removing smoke and acid constituents from flue gases read on January 7 to a joint meeting of the Institute of Fuel and the Institution of Electrical Engineers by Dr J L Pearson, G Nonhebel and P H N Ulander, it was stated that the daily combustion of 1,000 tons of average coal in addition to grit, dust and tarry matter, leads to the formation of 45 tons of sulphuric acid, 3–7 tons of nitric acid and half a ton of hydrochloric acid It is clear that when wet washing is applied, a non-effluent system must be used The new system is a recirculating, non-effluent water system, from which the grit, dust and ashes are separated and removed as solids A pilot plant was erected at Billingham, and was subjected to a twenty-months' running test The water used was a hard surface water drawn from a local stream Lime was used as the alkali for most of the test, and chalk was used for the remainder. Very satisfactory results were obtained 97–99 per cent of the sulphur oxides

were removed, 90–93 per cent of the hydrochloric acid and 97–98 per cent of the grit and dust from the pulverised fuel boiler. The exit gas from the plant is so free from sulphur dioxide that it is practically odourless, although the sense of smell can detect a very minute trace of this gas

River Flow Records

THE paper on "Flow of the River Dee" (Aberdeenshire), by Capt W N McClean, read before the British Association meeting at Aberdeen last September, has been issued in pamphlet form, reprinted from *Engineering*, with a memorandum which indicates the progress made in the survey of the river subsequent to the original date of the paper, and an addendum illustrating the manner in which the records are to be set out in tabular form for publication The Dee has a catchment area of 790 sq miles to Aberdeen, and for the purposes of the survey it was divided into four subsidiary areas, with flow gauging stations at Balmoral, Donnet, Cairnton and Cults The author states that he has found that the summer flow in certain Scottish rivers of about 100 to 700 sq miles catchment, may be taken, roughly, as from 1/5 to 1 cu ft per sec per sq mile, according to area Flood flows are much more complicated. The author further notes the difficulty of measuring low flows with current meters, as they are at present not very reliable for velocities of less than 1 ft per sec He suggests the difficulty may be overcome in the future by a temporary contraction of the channel, so as to increase the velocity Two types of apparatus are in use on the Dee. namely, one in which the meter is suspended from a wire and another in which a rod is the means of support. It is known that, in turbulent flows, the wire-suspended meter tends to set to the current and to give excessively high values The combined use of the two methods enables a serviceable comparison to be made of their respective accuracies The records obtained should prove of great public utility and the co operation of two authorities directly interested, the City of Aberdeen and the Fishery Board of the Dee, has been secured in establishing the gauging stations Capt McClean points out that if there were a recognised association for these river records, the water interests would become subscribing members of the association, receiving the completed records in return for the standard tables of water levels prepared by themselves

Thunderstorms in Great Britain

THE third annual report of the survey of thunderstorms in the British Isles, entitled "Summer Thunderstorms", has been received (Huddersfield: Thunderstorm Census Organisation 2*s.* 6*d*) Much of it has been written by Mr S. Morris Bower, the honorary director of the Survey, but articles have been contributed by Sir C V Boys on "Progressive Lightning" and by S T E Dark on "Trees Struck by Lightning" The Survey is an amateur enterprise somewhat similar to what the British Rainfall Organization was in its early stages. Its development is doubtless made more difficult because the economic importance of the distribution of thunderstorms is, at present, less than that of rainfall. There is the further difficulty that the study of thunderstorms cannot be effectively prosecuted apart from the general study of synoptic meteorology, except in limited directions In the purely statistical problem of obtaining the best possible cartographical representation of the occurrence of thunder, the Survey had the advantage in 1933 of a number of voluntary observers—1,291—nearly four times greater than the number of full climatological stations co-operating with the Meteorological Office, an advantage greater than the numbers alone suggest in that the observers at official stations do not concentrate on one phenomenon This report deals with some of the statistical results obtained in 1933, and also includes maps showing the number of days on which storms occurred in different parts of the British Isles in each of the months April–September 1932 The frequencies shown give the number of civil days during which one or more thunderstorms pass over head, and are therefore not comparable with figures based on the international definition of a day of thunderstorm at any place as one on which thunder is heard at that place The article on "Trees Struck by Lightning" is accompanied by some interesting photographs showing spiral scoring of tree trunks; it can be seen that the lightning may descend the tree either in a left or a right hand spiral Sir C V Boys's article deals with photographic studies of the duration and length of individual flashes, their direction and velocity, and suggests means for initiating a flash by firing a rocket into the thunder cloud, to assist in studies of this kind

The Imperial Forestry Institute, Oxford

IN the tenth annual report of the Imperial Forestry Institute for the year 1933–34 (Oxford: The Holywell Press Ltd, 1934) it is stated that the number of students was still considerably below normal, owing to the stoppage of the recruitment for the forest services of the Colonial Office, though it compared favourably with the number of the previous year Apart from regular students, a number of forest officers, at home on leave, and others attended the Institute for short periods to work in the libraries and the laboratories The Institute is still short-handed so far as the staff is concerned. During the year, a decree was passed by the University allocating a site within the Parks area for the erection of a new building for the Department of Forestry, including the Imperial Forestry Institute. Some progress has been made in regard to preliminary plans and estimates for the building, but it has not yet been possible to commence building operations owing to lack of sufficient financial provision, this matter, it is said, is receiving further attention. The income of the Institute is made up of grants from the Crown Agents, Dominions and others, Forestry Commission, and the Department of Scientific and Industrial Research An interesting part of the report is given

to a record of the progress which is being made with the collection and identification of the species of the forest floras of the various Colonies and Protectorates Details are given under the Colonies grouped under West Tropical Africa, East Tropical Africa, South Central Tropical Africa, the South Temperate Region and a few other territories The report gives full details of the various branches of work upon which the Institute is engaged, including brief accounts of the tours abroad undertaken by the students and others attending the courses

Plant Breeding in the U.S.S.R.

THE Bureaux of Plant Genetics at Cambridge and Aberystwyth have published jointly a bulletin of 58 pages (price 3*s* 6*d*) on plant breeding in the Soviet Union. This is mainly a translation from the Russian of an address given by Prof W I. Vavilov at a conference on the planning of plant breeding and genetics investigations, held at Leningrad in 1932, and is followed by a detailed programme of work on different economic plants The congress effected a reorganisation of the various genetical institutions in Russia and the adoption of a new system of fourteen plant breeding centres This bulletin will be of service to all who are engaged in plant breeding, particularly on the practical side It sets forth in outline the immense collections of economic plant material which have been made by expeditions to many parts of the world, notably Afghanistan, Kashmir, Abyssinia, Mexico, Bolivia and Peru. These embrace more than 200 crops, including 29,200 living specimens of wheat, 13,000 of barley, more than 9,000 of maize, 1,000 of potatoes, etc There has resulted the conception of geographical centres for the production of varieties of many crops The work includes cereals, vegetables, fruit trees, medicinal and fibre plants, etc A series of new potato species with diverse characters and multiple chromosome numbers was found in the Andes The vast amount of breeding work in progress and projected during the second five year plan (1933–37) is outlined in the latter part of the bulletin.

Grassland Research

THE Imperial Economic Committee has issued its report (No 27) on grassland seeds (London H M Stationery Office 1*s* net). As grass may be regarded as the vital raw material of most of the produce of livestock, and farming and grassland products accounted for more than 20 per cent of the value of all imports into the United Kingdom in 1932, the importance of good grassland management cannot be overemphasised The discovery that local strains are, for their own locality, often superior to commercial strains as regards persistence and leafiness has opened the way for considerable improvements, but even greater advances are being made by the production of pedigree strains at the plant breeding stations If, however, economic benefit is to be gained from all this experimental work, far-reaching changes in organisation of the seed industry will be needed. The primary task is that of ensuring an adequate supply of stock seed of the pedigree strains and of maintaining them true to type when they pass in commercial quantities through the ordinary channels of trade, and to achieve this end the breeding stations will need to be supplemented by seed farms. In this connexion, the report gives particulars of schemes for seed certification and other methods which have been adopted in various countries, notably in Sweden, Canada and New Zealand, and the success with which such schemes have met suggests that districts such as Northern Ireland, where considerable quantities of rye-grass seed are produced annually, might benefit from a similar type of organisation if combined with the experiments now in progress with improved stock seed.

Farm Pumps

AN illustrated booklet entitled "Pumps for Farm Water Supply" by C A Cameron Brown of the Institute for Research in Agricultural Engineering, Oxford, has just been published (Oxford Univ. Press, price 1*s* 6*d*) Its appearance is opportune although plans for its preparation were made before the drought in 1933 and 1934 had rendered the question of rural water supplies such an urgent matter. The inquiry has been carried out particularly with the view of helping the farmer and isolated small country house dweller to obtain an adequate water supply from whatever source may be available at as low a cost as possible Small electrically driven pumps capable of delivering upwards of 250 gallons per hour are available at prices from £10 to £12 No pump should be installed without an assurance from the makers that it will give the performance required to meet the particular set of conditions in each particular case, but with this proviso they should prove entirely reliable The gravity tank is still the commonest, and probably the simplest, method of providing service, but the pressure-tank system has an advantage where the installation of a gravity tank presents constructional difficulty or is likely to be unsightly, but it is at a disadvantage in districts where electricity supply failures are frequent The actual running cost of these small pumps is low in comparison with the cost of public water supply in towns Test figures under working conditions show from 0 66 electrical units to 1 89 units per 1,000 gallons

Zoological Society of London

AT the monthly general meeting of the Zoological Society of London it was stated that the total number of visitors to the Society's Gardens during the year 1934 was 1,639,611, the receipts amounting to £50,969, an increase of £3,432 as compared with the previous year The total number of visitors to the aquarium during 1934 was 265,604, the receipts amounted to £9,063, which represents an increase of £242 as compared with 1933 The total number of visitors to Whipsnade Park during 1934 was 516,411; the receipts were £22,223, an increase of £3,463 as compared with the previous year

Books on Agriculture

THE literature devoted to agriculture and allied sciences is now so extensive that the recent issue by the Ministry of Agriculture of Bulletin No 78 entitled "A Selected and Classified List of Books on Agriculture" (6d net) will be very widely welcomed. The books listed, together with many others, English and foreign, and many sets of periodicals, pamphlets and bulletins of agricultural experiment stations from all parts of the world, may be freely consulted in the Ministry's Library at 10 Whitehall Place, S W 1, between the hours of 10 a m and 5 p m (Saturdays, 9 30 a m and 12 30 p m)

Announcements

WE regret to announce the death on January 16, at the age of seventy nine years, caused by an accident while crossing a road in London, of Dr F A. Dixey, F R S , formerly subwarden, bursar and lecturer of Wadham College, Oxford, and president of the Entomological Society in 1909–10

ON February 5, Brigadier M N MacLeod becomes director-general of the Ordnance Survey Department, Southampton, in succession to Brigadier H St J L Winterbotham, who has held the post since August, 1930

PROF E V. APPLETON, Wheatstone professor of physics in King's College, London, has been elected a corresponding member of the Prussian Academy of Sciences (Physico-Mathematical Class)

PROF OTHENIO ABEL, lately professor of palæontology and palæobiology in the University of Vienna, has been appointed ordinary professor of geology and palæontology in the University of Göttingen, and director of the Geological and Palæontological Institute and Museum of the University.

THE Progress Medal of the Royal Photographic Society of Great Britain has been awarded to Mr Harold Dennis Taylor in recognition of his inventions, researches and publications in optical science, which have resulted in important advances in the construction of photographic lenses and in the development of photography

THE Council of the Institution of Naval Architects has awarded the gold medal for the year 1934 to Vice-Admiral Y Hiraga, professor of naval architecture and applied mechanics in the University of Tokyo, for his paper "Experimental Investigations on the Resistance of Long Planks and Ships", and the premium to Prof B. P Haigh, of the Royal Naval College, Greenwich, for his paper, "Further Tests and Result of Experiments on Electrically Welded Joints in Ship Construction". The medal and premium will be presented at the opening of the annual general meetings on Wednesday, April 10, at the Royal Society of Arts, John Street, London, W C 2

AT a reception given at the Collège de France on January 6, to the Assemblée de Médecine générale, addresses in memory of Claude Bernard, who made physiology the foundation of medicine, were delivered by Profs Mayer and D'Arsonval A visit was afterwards paid to Claude Bernard's laboratory in the Collège de France, where his table, instruments, early writings and manuscripts of his works are preserved

AT the annual general meeting of the Royal Meteorological Society held on January 16 the following officers were elected *President*, Lieut -Col Ernest Gold , *Vice Presidents*, Prof David Brunt, Dr A Crichton Mitchell, Dr F J W Whipple and Mr W M Witchell ; *Treasurer*, Mr R A Watson Watt , *Secretaries*, Dr John Glasspoole, Mr Eric Ludlow Hawke, Mr M McCallum Fairgrieve ; *Foreign Secretary*, Mr Charles J P Cave , *New Members of Council*, Mr E G Bilham, Mrs Charles J. P Cave, Mr C S Durst, Sir Gilbert Walker.

AT the meeting of the Royal Microscopical Society on January 16, the following officers were elected *President*, Prof W A. F Balfour-Browne , *Vice-Presidents*, Mr J E Barnard, Mr Conrad Beck, Mr D M Blair, Dr R S Clay , *Hon Treasurer*, Mr C F Hill , *Hon Secretaries*, Prof R T Hewlett, Mr J Smiles , *New Members of Council*, Mr M T Denne, Dr G M Findlay, Dr E. E Jelley, Mr. J Milton Offord , *Hon Editor*, Dr G M Findlay , *Hon Librarian*, Dr. Clarence Tierney , *Hon Curator of Instruments*, Mr W E Watson Baker , *Joint Hon Curators of Slides*, Mr. N I Hendey, Mr E J Sheppard

THE Jenner Memorial Medal for 1934 has been awarded to Sir George Buchanan, vice-president of the League of Nations Health Committee and Master of the Society of Apothecaries of London, 1934–35 The Jenner Memorial Medal was founded by the Epidemiological Society (now merged in the Royal Society of Medicine as the Section of Epidemiology and State Medicine) in "recognition of the greatest medical service ever done to man", in 1896 on the occasion of the Jenner centenary It is awarded by the Council of the Royal Society of Medicine on the recommendation of the Section for distinguished work in epidemiological research or for pre-eminence in the prevention and control of epidemic disease.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :—An agricultural organiser for the Wiltshire County Council—The Clerk, County Offices, Trowbridge (Jan 31). An assistant for research on bonding materials in foundry sands in the British Cast Iron Research Association—The Director, 21 St. Paul's Square, Birmingham, 3 (Feb 8). A senior lecturer in physics, two lecturers in mechanical engineering, an instructor in workshop practice and drawing, and an instructor in carpentry, building construction and geometry at the Lester School and Institute, Shanghai—The Lester Trust, Messrs. Viney, Price and Goodyear, Empire House, St. Martin's-le-Grand, London, E.C.1 (Feb. 25).

Artificial Radioactivity Produced by Neutrons

IN the course of recent work in radium beam therapy research, we had the opportunity of making investigations in artificial radioactivity induced in some of the heavier elements through the agency of neutrons

We had available a tube containing 500 mgm of radium mixed with 2 gm of finely divided beryllium This source, and the element to be made radioactive, were immersed in a water bath to obtain the intensification of activity reported by Fermi and his co-workers, and interpreted by them as being due to neutrons slowed up by impact with the hydrogen nuclei of the water The strong source used, and this method of obtaining intensification, permitted us to measure half lives with fair accuracy in the case of elements previously reported weakly active The following results were obtained

Molybdenum	(1)	25 minutes
	(2)	Roughly 36 hours
Palladium	(1)	14 hours
Tantalum		Very slight activity after exposure for 24 hours
Tungsten	(1)	24 hours
Platinum	(1)	36 minutes

The distribution of slow neutrons around the 500 mgm source immersed in 60 litres of water was studied by measuring the activity excited in a silver tube Between 5 cm and 10 cm from the source, the activity fell off as the inverse first power of the distance, while between 15 cm and 30 cm the activity fell off roughly as the inverse fourth power The edge of the water bath was about 30 cm from the neutron source. This may account for the rapid falling off observed at the greater distance The slowed up neutrons could not be detected 2 seconds after the source was removed.

We also had available three small tubes each containing 100 mgm. of radium In one there was 100 mgm of beryllium; in a second 100 mgm of boron; and in the third 100 mgm. of aluminium. In each case the metal was finely divided, and was intimately mixed with the radium associated with it The radioactivity produced in iodine by each of the three tubes was compared, with the following results.

	Neutron source	Activity excited in iodine (relative)
Tube 1	Radium and beryllium	13 0
Tube 2	Radium and boron	4 5
Tube 3	Radium and aluminium	1 0

The activity produced in a silicon tube by the smaller radium and beryllium source was measured under similar conditions in air and in water. The water reduced the activity by a factor 0·6, in contrast to its effect with silver, when a great increase in activity occurred. The thickness of water between the neutron tube and the concentric silicon tube was 1·4 cm

A Spectroscopic Method for Detecting some Forms of Chelation

ABNORMALLY large differences in solubility and volatility between isomers of some disubstituted benzene derivatives have been explained by Dr N. V Sidgwick as arising from the presence of chelate rings in the anomalous compounds These rings are considered to be formed between ortho substituents and usually to contain six atoms, one of which is hydrogen situated between two oxygen atoms The ease with which such rings can be ruptured has prevented a demonstration of the phenomenon by the usual methods of organic chemistry In the course of a quantitative study of the infra-red absorption coefficients of a series of organic molecules, which is in progress in this laboratory[1], an apparently specific behaviour has been found for this type of chelated compound

Organic molecules containing OH, NH, SH or CH show, in the near infra-red, absorption which is characteristic of the presence of these groups Two illustrative spectrographic records of absorption due to the presence of OH, NH and CH are contained (on p 3575) in the first report[1] of the above mentioned research In these studies, on which a second report is now being prepared for publication, it has been found that the absorption (area under the absorption coefficient against frequency curve) in the vicinity of 1 4–1 6 μ due to one NH or to one OH group, shows variations which are not very large even among molecules of widely different types These variations are, however, by no means negligible Actually the difference in area so far observed is such that the largest is less than three times the smallest Since, however, in most cases an absorption of one fiftieth of the mean value could be detected with reasonable certainty, this characteristic absorption can probably be used with confidence in detecting the presence or absence of these groups in organic molecules. This forms the basis of the method here proposed for detecting some forms of chelation, the absence of such OH absorption in molecules showing OH by ordinary chemical tests being taken as indicating chelation through hydrogen. The variations in the area under the absorption curve constitute one of the quantitative differentiating factors which have been developed in the above mentioned research in an attempt to build an analytical method Variations occur also within any one group such as OH or NH in the position of the absorption, as well as in the shape of the absorption curve, the latter being particularly striking In those of the compounds discussed below which show OH absorption, pronounced variations in all three of these factors occur, and they may all be important in the matter of chelation, but their significance requires further study for its interpretation.

Particular examples of compounds that have been examined in the above manner and found to give no absorption characteristic of molecules containing

OH are: salicylaldehyde, *o*-nitrophenol and 2, 6-dinitrophenol, which have properties typical of chelated substances[2], methyl salicylate and *o*-hydroxyacetophenone which, although not previously tested, are representative of Prof. Sidgwick's Type B[3], and salicyl-α-methyl-α-phenylhydrazone and γ-diethylaminopropanol. While there has been no prior consideration of the last two compounds as chelated, in each of them the condition of a six membered ring is fulfilled, however, with nitrogen replacing oxygen. Benzoin and 8-hydroxyquinoline, which form chelated salts[4], give characteristic OH absorption, as also do ethyl lactate and diethyl tartrate. These last compounds apparently are doubtful cases of chelation, the first three require five membered rings and in the last one either five or six membered rings are possible.

Characteristic OH absorption was found in *p*-hydroxybenzaldehyde, *m*-nitrophenol, *p* hydroxyacetophenone, *o*-chlorophenol, and 2, 4, 6-trichlorophenol, which were selected, from the OH compounds that we have examined, as non chelated compounds comparable to the first five of the above mentioned substances. 2, 4, 6 Trichlorophenol is further of interest in that the OH group is so placed as to be 'sterically' affected in reactions. It is probable, for physico chemical reasons, that neither these nor the preceding observations have been influenced by association since the solutions are of the order of 0 01 molal.

Surface-force Theory of Crystal Rectification

EXPERIMENTS with Mr A. K Das-Gupta have shown that when carborundum, zincite or silicon crystal is placed between two mercury electrodes giving a large contact area, there is considerable rectification. Similar experiments with symmetrical crystals like iron pyrites, galena, etc, have shown no rectification. These experiments strongly suggest asymmetric conductance in crystals having no centres of symmetry. Accordingly, crystal detectors can be classified thus (1) crystals having centres of symmetry, and (2) crystals having no such symmetry. In the symmetrical crystals, we observe rectification associated with point contacts. In the second group, in addition to this 'point'-rectification, there is *volume* rectification, due to asymmetric conductance. The object of the present note is to suggest a theory of rectification in the *symmetrical crystals*.

In an ionic crystal (like iron pyrites, galena, etc), if we take a plane where *similar* sets of ions are placed at regular intervals, it is evident, if we consider the first layer and the next, that any ion on the surface has an unbalanced electrostatic force. When an alternating voltage is applied to the surface of a crystal where crystal planes parallel to the surface contain similar sets of ions, this electrostatic force on the surface would give rise to a unidirectional current. The crystal plane in the first layer may contain *all* positive or *all* negative ions. Both positive and negative rectification effects are therefore possible. In planes which contain oppositely charged ions *alternately*, the 'whisker' is in contact with a large number of such ions, thus giving, on an average, no rectification. This is what is actually observed in natural poly-crystals.

Of the two features in the current-voltage characteristic curves, namely, (1) asymmetry and (2) curvature, the first is explained in the symmetrical crystals in terms of the electrostatic force on the surface, the second is due to

(1) local heating at the junction, as pointed out by Eccles[1], and

(2) the effect of strain on the crystal, as explained by Dowsett[2].

A small contact area for the 'point' rectification is necessary, because a large contact area means a large number of small contact points of varying degrees of rectification giving on the average a small effect. Besides, for some points, the contact resistance is extremely small, causing more or less a short circuit.

The surface-force theory can explain the following experimental results obtained in this laboratory:

(1) Rectification observed in the case of symmetrical crystals in contact with pointed crystals of the same composition. (Eccles's thermo-electric theory[3], and Schottky's electronic theory[4], fail to explain these results.)

(2) Decrease of rectification on heating the crystal.

(3) Decrease of rectification on heating the junction in the case of symmetrical crystals.

(4) Decrease of rectification on exposure to ultraviolet light and X-rays.

Synthesis of Vitamin C by Luteal Tissue

MOURIQUAND and Schoen have shown[1] that gravid female guinea pigs on a scorbutic diet develop scurvy only very slightly or not at all. They considered that the fœtus was capable of synthesising vitamin C, and thus protected the mother from incurring the disease. Afterwards, Rohmer, Sanders and Bezssonoff[2] and Rohmer, Bezssonoff and Stoerr[3] showed that the young human infant, up to the age of five months, is capable of synthesising vitamin C.

It appears from these results, therefore, that the fœtus almost certainly synthesises vitamin C in fairly large amounts. It is known that the corpus luteum possesses a high concentration of the vitamin in its cells, and the question arises whether presence of the vitamin in this situation is the result of its manufacture by the fœtus, or whether it is the result of the intake of vitamin C in the food.

It was decided to endeavour to create a corpus luteum in an experimental animal with the aid of the luteinising hormone of the anterior pituitary, in order to ascertain whether this would protect the animal from scurvy induced by a scorbutic diet.

The chief difficulty was in the choice of animal.

Rats, mice and rabbits are the most suitable animals on which to use the luteinising hormone, but they possess the ability to synthesise vitamin C to varying degrees The guinea pig, while being an admirable subject for tests in connexion with scurvy, does not readily respond to the luteinising hormone It was found, however, that in guinea pigs, injections of fifty rat units of antuitrin S for three days, while it did not produce a definite corpus luteum, caused considerable luteinisation of groups of cells These cells also possessed the power of reducing silver nitrate.

Three groups of animals were then placed on a scorbutic diet (*a*) pregnant females, (*b*) young virgin females, untreated, (*c*) young virgin females receiving fifty rat units of antuitrin S a day subcutaneously (50 rat units = 0 5 c c antuitrin S) The diet consisted of bran and pollen, olive oil, wheat germ, Radiostoleum, common salts All the animals lost weight on this diet At the end of a fortnight, all the untreated animals had died of typical scurvy—their adrenals giving no reaction with vitamin C

The treated animals, although having lost considerable weight, were active and showed no signs of scurvy, although two had died of an acute infection The pregnant animals appeared much the same as when the experiment started and had lost very little weight

The results of this experiment suggest that the luteal tissue is capable of synthesising vitamin C, it does not disprove the synthesis of vitamin C by the fœtus It is probable that the synthesis takes place first in the corpus luteum and, once the fœtus is developed, it either takes over, or supplements, the vitaminogenic function of the luteal tissue[*]

Activation of Cambial Growth

EVIDENCE was recently obtained by one of us[1] indicating that the influence coming down from the leaves, which activates cambial growth, is a hormone Also Laibach[2] has caused decapitated epicotyls of *Vicia Faba* and various leaf-stalks to grow in thickness by placing on them the pollinia of orchids, which he has shown to exude large quantities of auxin, the hormone which promotes the elongation of stems, but he has not stated what anatomical changes were involved We have now been able to activate cambial growth in decapitated strips of young sunflower hypocotyls, by inserting the upper ends of the strips into a 0·02 per cent solution, in 25 per cent gelatine, of the ether-soluble component of urine, which is known to contain abundant auxin[3] The gelatine containing the extract was applied in short pieces of glass tube while warm and liquid, and quickly set to a gel It contained a little thymol (1 in 100,000), and was renewed every three days.

After 19 days, the parts covered by the gelatine had all formed cambia, which were in the normal positions and had grown very strongly, one of them having formed more than twelve layers of secondary xylem These parts had also, quite unexpectedly, formed numerous roots A few millimetres below the gelatine, also, there had been distinct cambial growth, though at this level it was very much less In controls, gelatine and thymol without the extract did not cause any cambium or roots to be formed The results raise the question whether, in spite of some indications to the contrary[1,4], the hormone activating cambial growth is the same as auxin The experiments will be continued

We are much indebted to Dr Weisberger, of the organic chemistry laboratory, Oxford, for kindly showing us how to extract the ether-soluble component by the method of Kogl and collaborators[3]

Recession of the Spiral Nebulæ

THE very recent and inspiring work of Prof E A Milne on world structure has led us to investigate whether there exists a law connecting the velocity and distance of a particle from an observer which is invariant for the generalised Lorentz transformation. In the usual notation, the only law of the form $f(x_1, x_2, x_3, x_4) = 0$ which is invariant for the infinitesimal Lorentz transformation is known to be $x_1^2 + x_2^2 + x_3^2 + x_4^2 = 0$, which gives the propagation of light Following this, we have investigated whether there exists a law of the form $\varphi(x_1, x_2, x_3, x_4, u, v, w) = 0$ which is invariant for the generalised Lorentz transformation, here $u = dx_1/dx_4$, $v = dx_2/dx_4$, etc In its generalised form the transformation is

$$\begin{aligned} x_1' &= x_1 + (hx_1 + ax_2 + bx_3 + cx_4) \\ x_2' &= x_2 + (ax_1 + hx_2 + dx_3 + ex_4) \\ x_3' &= x_3 + (bx_1 + dx_2 + hx_3 + fx_4) \\ x_4' &= x_4 + (-cx_1 - ex_2 - fx_3 + hx_4), \end{aligned}$$

$$\text{and } u' = \frac{u + (hu + av + bw + c)}{1 + (h - cu - ev - fw)},$$

similarly, v', w' may be obtained h, a, b are the constants of the transformation We have found that the following set of equations is the only invariant set of this type, that is, involving both velocities and co-ordinates

$$\frac{u}{x_1} = \frac{v}{x_2} = \frac{w}{x_3} = \frac{1}{x_4} \qquad (1)$$

The corresponding equations for u', v', w' follow immediately from (1)

The importance of (1) may be judged from the fact that, next to the equation of light, the most fundamental relation hinged upon the Lorentz transformation is the distance-velocity relation (1), which has been expressed by Milne in the form $v = r/t$.

It is natural to expect that a relation of this nature should hold good only in the outer regions of space where the island universes are too far

removed from each other to cause any appreciable departure from this law It is, at any rate, unreasonable to expect the law to hold good in the central galaxy itself because of the powerful gravitational field in it

Dec 17

THE recession law, $v = r/t$ in combination with the density-distribution law $n\,dx\,dy\,dz = Bt\,dx\,dy\,dz/(t^2 - r^2/c^2)^2$, can be shown to be a valid description of a certain system of particles in motion on *any* relativistic law of gravitation This was the subject of my lecture to the London Mathematical Society, "World Gravitation by Kinematic Methods", delivered on May 17 last (see NATURE, May 26, 1934, p. 789) A full discussion of this subject is given by me in a volume now passing through the press

E A MILNE

Rotational Raman Effect in Gases: Carbon Dioxide and Nitrous Oxide

IN the course of a detailed investigation of the rotational Raman effect in gases, we have obtained the following significant results with carbon dioxide and nitrous oxide In Fig 1 are shown photomicrometric records of the rotational wings obtained with carbon dioxide gas at pressures of about 6 and 50 atmospheres respectively The exposure times are so adjusted that the intensity of the wing is nearly the same in both cases It may be noticed that in the low pressure record, the wing exhibits distinctly a position of maximum intensity, shown by the arrow, and then fades off until it merges into the Rayleigh line

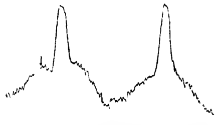

FIG 1 Photomicrometric records of the rotational wings with carbon dioxide at pressures of 6 atmospheres (left) and 50 atmospheres (right)

A quantitative investigation reveals that both the position of the intensity maximum and the distribution of intensity within the wing are in good agreement with theory On the other hand, in the high pressure record, no such maximum is visible and the wing is relatively more intense in the region lying between the position of the maximum and the Rayleigh line It is of significance that these features which are characteristic of liquids[1] make their appearance also in gaseous carbon dioxide, but only at the higher pressure Exactly similar results are obtained by us with nitrous oxide working at 6 and 40 atmospheres respectively. Such phenomena are evidently connected with the fact that, at the higher pressures, the gases investigated are very near their critical states, thus resembling the liquids in certain respects.

It may be of interest to note here that our measurements of the intensity maxima at low pressures give 69×10^{-40} and 62×10^{-40} respectively for the moments of inertia of CO_2 and N_2O molecules, as against $70 \cdot 1 \times 10^{-40}$ and $59 \cdot 4 \times 10^{-40}$ deduced earlier from infra-red absorption[2].

Development of the Lightning Discharge

SOME months ago, B F. J. Schonland and H Collens[1] published several important photographs of lightning discharges taken by a Boys' camera, that is, two lenses fixed at opposite points of a circle and revolving rapidly about its centre In a further communication, with D F Malan, published in NATURE[2], a brief account is given of some further results with their camera The most important point which emerges from a consideration of their new photographs is that there is a characteristic difference between the predischarges of the first stroke of a lightning flash and those of the subsequent strokes of the flash along the same track. While the latter predischarges are of a continuously moving character and travel from cloud to ground generally in less than 1/1,000 of a second, the former move from the cloud in a discontinuous step by step manner and take a comparatively long time to reach the ground, sometimes more than 1/100 of a second

I would remark here that this manner of the first development of the track of an electric discharge through normal air was shown by me for the laboratory spark so long ago as 1898[3] and for the lightning discharge in 1902[4], in both cases using moving photographic plates to analyse the discharges

Moulting and Replacement of Feathers

IN a recent publication, Dr. Lowe[1] has described the peculiar moulting of penguins as due to new feathers pushing out their predecessors in rather widespread areas, and regards this as a unique feature of Sphenisciformes Moulting in patches is certainly a rare occurrence under normal conditions in the majority of birds, but a new feather growing at the base of the old feather is the usual method of replacement during the moulting period. Dr. Lowe further says: "the intrusion of the tip of the new feather through the lower umbilicus of the old is interesting, because in birds in general as soon as the growth of the feather becomes an accomplished fact the lower umbilicus at the base of the calamus is definitely sealed, making the entry of a new feather an impossibility". He continues by using this as one of the reasons for regarding the penguin as primitive rather than degenerate, and quotes Gadow that the

only known exception to this general rule is in *Struthiones*, where the old feather is carried for some time at the tip of the new

Although statements have recently been made (Lillie and Juhn[1]) saying that it is not yet known whether the pulp of a feather resumes activity prior to shedding of the old feather, it is a well-known fact (Lynds Jones[3], Cossar Ewart[4] and others) that in young chicks and ducklings, the first generation feather is carried for some time at the tip of the succeeding definitive feather Again, in adult fowls and ducks, if feathers are plucked near the moulting period, the new feather is invariably pulled away attached to its predecessor This is unavoidable owing to the method of formation of the new feather. In nestling down, there is definite continuity between barbs of the new feather and the calamus of the old one, and in addition, the developing barbs are so constricted within the calamus of the old feather, that they usually show a distinct curve distally for some time after the old feather has been shed

In definitive feathers, the new feather is always formed within the base of the old (except, of course, during regeneration following deliberate plucking) This is due (*a*) to the outermost intermediate cells of the 'collar' cornifying to form the base of the calamus, instead of the whole of the stratum intermedium cornifying *en masse*, as it does more distally, while (*b*) the median layers form a second sheath within the calamus, and (*c*) the innermost layers form the ridges from which the barbs of the new feather arise This process is described in detail in a paper now in press

From this method of replacement of a feather, the lower umbilicus could not be completely sealed when the feather is fully grown It is true that feather caps form as the pulp withdraws when the feather is nearing maturity, but these do not extend to the actual base A minute papilla projects within the inferior umbilicus while the feather is attached to the bird, limited in its extension by the last feather cap, and it is from this papilla that the new feather grows If the old feather is plucked when fully mature, but before the new feather has commenced to form, then this remnant of the previously extensive pulp is left behind in the follicle, so that the impression of an entirely pulpless and sealed feather is obtained.

It is therefore clear that these facts of the inferior umbilicus of the feather remaining unsealed, and the new feather pushing out the old, cannot be regarded as peculiar to Sphenisciformes or to Struthioniformes

Occurrence of *Limnocnida* in the Periyar Lake, Travancore

ON June 4 last, I was surprised to find a number of fresh-water medusæ in the Periyar Lake in Travancore From the shape of the manubrium and the presence of the gonads on the manubrium, and the shape and the arrangement of the nematocysts, the medusæ undoubtedly belong to the genus *Limnocnida* which has previously been recorded from India. The Periyar Lake, about ten square miles in extent, has been formed by damming at its source in the Western Ghats the River Periyar, which flows westwards. Although the river fluctuates with the seasons, the lake contains deep water all the year round It is noteworthy that fresh-water medusæ were found by Mr. S P Agharkar, but were in a river system which flows eastwards across the continent and enters the Bay of Bengal

The Periyar Lake is situated at an elevation of three to four thousand feet and is sixty miles from the west coast of India as the crow flies All the medusæ I saw were about the same size and very much smaller than those discovered by Mr Agharkar Mr Agharkar's specimens measured 1·75 mm when young, 15 mm when adult The smallest of my specimens, however, measures 4 2 mm in diameter and the largest 4·9 mm in diameter and 2 2 mm in height, with tentacles measuring 1 6 mm So far, they have received only a cursory examination

I believe the occurrence of *Limnocnida* has only been recorded from one area in India previously, that is, in the headwaters of the Kistna River and the neighbourhood, 650 miles from Periyar Whether the species inhabiting the Periyar Lake is the same as that described by Dr Annandale or a new species can only be determined after a proper examination of the collection

Local Variation in Habits of the Lizard, *Amblyrhyncus cristatus*

ON a recent visit to the Galapagos Archipelago I noticed a point concerning *Amblyrhyncus cristatus*, an aquatic species, which might be of interest as a footnote to Darwin's observations on the same reptile

In "The Voyage of the *Beagle*", Darwin says "I several times caught this same lizard, by driving it down to a point, and though possessed of such perfect powers of diving and swimming, nothing would induce it to enter the water, and as often as I threw it in, it returned in the manner above described".

I tried this same experiment myself on Albemarle Island, and found the reptile returned to dry land at great speed, but on Indefatigable Island, on the contrary, the lizards not only held no prejudice against entering the water, but even proceeded to do so as quickly as possible on being approached—a curious example of local variation

Darwin attributes their reluctance to enter the water to the presence of sharks, but it is singular that I found sharks more numerous around Indefatigable Island than elsewhere in this archipelago.

Simultaneous Travel of a Surge of Stress and a Group of High-Frequency Waves of Stress in a Steel Wire

IN previous communications, it has been shown how the frequency of longitudinal vibration of a steel wire may be measured[1] and also how the speed of travel of a surge of stress in a steel wire may be measured directly[2]. From each of these methods the value of Young's modulus may be found, and the

values so obtained are in close agreement with each other and with the value obtained by the static method.

Experiments have recently been made in which a surge of stress and a group of high-frequency waves of stress were caused to travel simultaneously along a steel wire For this purpose, a hard drawn steel wire as used in colliery winding ropes was obtained of a total length of about 500 ft and diameter 0 123 in. The wire was firmly clamped near one end by means of three clamps spaced about 18 in. apart About 50 ft. from this end the wire passed through a solenoid and search coil, and a second exactly similar solenoid and search coil was arranged at a distance of 268 3 ft along the wire from the first solenoid, the free length of wire beyond the second solenoid being 185 7 ft The solenoids were connected in series and excited by direct current The two search coils could be connected in series through a valve amplifier to the oscillograph or each coil could be used alone when so desired A 500 frequency standard tuning fork was used to provide the timing wave

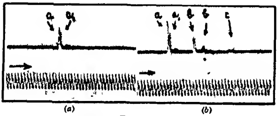

FIG 1

In the first test, the search coil of No 1 solenoid was used alone When the wire was struck at the clamped end the oscillogram shown in Fig 1*a* was obtained It will be seen that a group of high-frequency waves is superposed at a_1 on the surge a, this group being due to the longitudinal vibration of the clamped sections of the wire There are also smaller groups of waves which pass through the solenoid later, but after about 0 016 sec no further disturbances pass In Fig 1*b* is shown the oscillogram which was obtained when the two search coils were connected in series and a blow was struck at the clamped end of the wire It is now seen that the group of high-frequency waves again appear at a_1 superposed on the surge at a. When, however, the disturbance has reached the second search coil, the surge and the group of waves have become widely separated as shown at *b b*, so that the group is travelling at a much lower speed than the surge The peaks at *c* are due to the reflexion of the surge at the distant end of the wire returning through the second solenoid

It is not clear why the group of waves should travel at a speed so much slower than the surge Experiments with an annealed wire indicate that the speed of the group is more nearly equal to that of the surge Further experiments are being made to observe the effects on this phenomenon of the frequency of the waves in the group

Accuracy of the Curie-Chéneveau Magnetic Balance

IN a letter to NATURE[1] and also in a recent Royal Society paper[2], F E Hoare mentions difficulties that he has had with the Curie-Chéneveau magnetic balance and states that after a trial of some months he has decided to abandon the use of this instrument He concludes that it is "almost impossible" to place the specimen always in exactly the same position in the field and he thinks that he can thus explain "the unaccountable changes in the deflexion for water obtained from time to time" by Gray and Dakers[3] and described by them in the words just quoted These unaccountable variations, however, are in many cases observed even when the tube has not been removed from the beam between readings, and in any event do not exceed 1 per cent, whether the question of position is involved or not Instead of the 20 per cent of Hoare, the variations observed in this Department are thus of a much smaller order, even with the balance in its crudest form, and probably are due to a different cause The instrument is free even from this small irregularity in its normal working condition. Both the steadiness attainable and the ease with which the position can be adjusted, with reasonable care, are indicated by the latest measurement made in this department by one of us (J H C)

Deflexions were read for four separate fillings with water and four separate fillings with ethyl nitrate It was impossible to detect the slightest difference between the four water readings each was 16 00 ± 0 01 cm for tube + water Similarly, the four readings for tube + ethyl nitrate were identical, namely, 12 30 ± 0 01 cm, in every case, with not the slightest variation The eight measurements were done in 2½ hours

Hoare directs attention to the discrepancies between the results of Gray and Dakers[3] for rubidium bromide and those of Ikenmeyer[4], although from his recent paper[2], when he compares his own results with those of Ikenmeyer, he has a rather poor opinion of the latter as standards for comparison Gray and Dakers' results are supported, however, by Pascal[5], the sum of whose atomic values, 57 8, is much closer to the 56 69 ± 0 54 of Gray and Dakers[3] than to the 65 5 of Ikenmeyer (quoted by Hoare) or to the 62 9 of N Crow[6] Pascal adopted non torsional methods, and to compute his atomic values utilised at least nine substances

The usefulness of this instrument, however, does not depend upon a few isolated instances Numerous results of high precision have been obtained, and confidence in these results is further strengthened by the adaptability of the data to interpretation There must be reserved for a future communication a fuller account of results achieved with the balance and also a description of improvements in the apparatus and in the details of its manipulation It is hoped, in this way, to put our experience at the disposal of those prepared to give the instrument a trial

Disintegration by Slow Neutrons

CHADWICK and Goldhaber, in their letter to NATURE on January 12, record experiments which indicate that slow neutrons can eject heavy charged particles from light atoms, even when the neutron traverses the atom "at relatively large distances" from the nucleus. To account for this, they suggest that there may be an attractive force between a nucleus and a neutron, at these large distances.

An alternative explanation is that the heavy particles are not in the nucleus, but outside it.

Velocity of Sound in Liquid Oxygen

IT seems that the velocity of sound has never been measured in liquefied gases at low temperatures, probably because the customary methods were not easily practicable. It appeared reasonable to try as a new method the effect, which has recently been discovered by Debye-Sears and Lucas-Biquard, namely, the scattering of light by ultrasonic waves in liquids and solids. Judging from the results which I have obtained using oxygen as a scattering liquid, this method provides indeed a simple and convenient means for this purpose. The experiments, which were carried out with oxygen of 99.3 per cent purity, boiling at atmospheric pressure (705–720 mm. mercury) at $-183.6°$ C., and with a frequency of 7,500 kilocycles, yielded a sound velocity of 903 m./sec. Taking 1.140 as the density of the liquid, one gets then an adiabatic compressibility of 105.6×10^{-6} cm.^{2}/kgm. The isothermal compressibility may also be calculated, with 3.38×10^{-3} as the value of the differential of the specific volume, and 0.406 as the specific heat at constant pressure, it comes out as 172.0×10^{-6} cm.^{2}/kgm.

A detailed account will appear in *Helv. Phys. Acta*.

Points from Foregoing Letters

BY means of a powerful source of neutrons (half a gram of radium mixed with beryllium) Prof. J. C. McLennan, Mr. L. G. Grimmett and Mr. J. Read have produced measurable radioactivity in the elements molybdenum, palladium, tantalum, tungsten and platinum. They have determined with fair accuracy the radioactive life-periods thus induced in these elements.

The amount of absorption of infra-red light (1.4–1.6μ) by certain organic substances can be related to their molecular structure as deduced from chemical tests, solubility, volatility, etc. Dr. Hilbert and Messrs. Wulf, Hendricks and Liddel state that when a hydrogen atom of an organic molecule is joined to two oxygen atoms by a co-ordinate link (that is, it forms a 'chelate' ring by sharing two electrons of one of the oxygens) then the compound does not show the usual amount of infra-red absorption typical of ordinary compounds containing the OH group, although by chemical tests the OH group appears to be present.

Crystals without a centre of symmetry (carborundum, zincite) when placed between two mercury electrodes, can be used as radio-detectors, while symmetrical crystals (galena, pyrites) do not give rectification with such large contact areas, but only with point contacts (cat's-whisker). Dr. S. R. Khastgir outlines a theory based upon the arrangement and the unbalanced electrostatic forces of the atoms in the surface layers of the crystals, and claims that this theory explains a number of observations not accounted for by other views of crystal rectification.

It has been shown that infants can produce their own vitamin C. From experiments with female guinea pigs in which luteal tissue was artificially induced, Dr. Geoffrey Bourne deduces that the corpus luteum of the ovary also has the ability to synthesise the anti-scorbutic vitamin C.

Mr. R. Snow and Mr. B. Le Fanu find that the cambium cells from strips of decapitated young sunflower plants, not only continue to grow, but even produce wood cells (xylem) and give off roots, when covered with gelatin containing auxin (from the ether-soluble extract of urine). This raises the question whether the hormone activating cambial growth may not be identical with auxin, which has been shown to promote cell elongation and root formation.

Prof. V. V. Narlikar gives an equation, which he states to be the only one, relating space time *and velocity* in such a way that the formula is invariant (independent of the observer's motion). From this formula the recession of spiral nebulæ can be deduced.

The distribution of intensity in the spectrum of the light scattered by gases at different pressures has been determined by Mr. S. Bhagavantam and Mr. A. V. Rao. They find that the 'wings' of continuous light, which appear at the sides of the primary line and have been ascribed to the rotation of molecules, become similar to those obtained with liquids, when the gases are under high pressure.

The replacement of feathers in fowls is described by Miss Anne Hosker, who points out that not only in penguins and ostriches, as mentioned by Dr. Lowe, but also with young chicken and ducklings, the first feathers during moulting are carried for some time at the tips of succeeding ones.

Dr. T. F. Wall reports that in a hard-drawn steel wire, with one end clamped by three clamps 18 in. apart, a group of high-frequency waves of stress (produced by a blow at the clamped end) was found to travel along the wire more slowly than the simultaneous surge of stress. In an annealed wire, the speed of the group of waves is more nearly equal to that of the surge.

Dr. F. W. Gray and Mr. J. H. Cruickshank defend the accuracy of the Curie-Chéneveau magnetic torsion balance; they do not agree with F. E. Hoare that the unexplained variations observed at times by Gray and Dakers with water are due to the unreliability of the balance.

Research Items

Origins of Morris Dance. The question of the origins of the Morris dance and of its name is once more raised by Mr Rodney Gallop (*J. English Folk-dance and Song Soc*, 1, No 3) The belief generally held that 'Morris' was a corruption of 'Morisco' and the dance itself of Moorish origin was doubted so long ago as the time of Strutt, who in his "Sports and Pastimes of the People of England" suggested that it was derived from a part of the ceremony of the Feast of Fools, but Francis Douce in 1839 tried to justify the traditional view, while recognising that the European Morris differed widely from the true Moorish dances Cecil Sharp at first (1906) adopted Douce's view, but later (1912) held that it was a development of a pan-European, or even more widely, distributed custom He held, however, that the name might still be derived from 'Morisco', but without any implication of origin It was a popular 'explanation' of the blackened faces of the dancers It is now pointed out that 'Morisco' is applied to a wide diversity of dances, first appearing in the fifteenth century in France, Burgundy and Italy. In England, from the sixteenth century onward, it is both a court dance and a folk-dance No single feature is common to all, the two widespread elements, the blackening of the face and the use of bells, to which attention mainly has been directed, being by no means universal In numerous ceremonial combats, the opponents are 'Christians' and 'Moors'. These combats were of wide distribution and still survive in Portugal and on the east side of the Adriatic, and they have been carried to Panama and Mexico The Morisco of the Hispanic peninsula does not always involve two sides and a combat Some are purely processional, though in origin obviously a survival of the pagan ceremonial combat One side has tended to disappear, and the survivors have retained the name of 'Moor', possibly as the equivalent of 'pagan' and as applied to a 'pagan' dance

New Fishes from New Jersey and Florida. Mr Henry W Fowler in his paper "The Buckler Dory and Descriptions of three New Fishes from off New Jersey and Florida" (*Proc Acad. Nat. Sci Philadelphia*, 86, 1934) describes an interesting new species of *Macrorhamphosus*, *M. otteri* which has before been confused with the Mediterranean *M scolopax*, but differs from it in the more advanced spinous dorsal origin and consequently longer interdorsal area, and in its deeper body *Parathunnus rosengarteni* n sp is also described from a mounted specimen angled by Dr Rosengarten in Florida waters, and recognised by him as a species distinct from any with which he was acquainted. This fish has a lateral golden band running along the whole length from eye to tail and measures 713 mm Another interesting new species is *Antigonia browni*, the depth of which is 1/5 greater than its length; it differs in many ways from its Barbados relative *Antigonia capros*, Lowe, the only other American species known The specimens of the Buckler dory, *Zenopsis conchifer*, establish its distribution over the western Atlantic, known from there previously only from the imperfect and immature *Zeus ocellata*, and indicate that it is likely to occur all along the region of the Gulf Stream

Culture of the Mantle-Wall of *Helix*. J. Brontë Gatenby, Joyce C Hill and T J. Macdougald (*Quart. J. Micro Sci*, 77, Pt 1, 1934) give an account of the technique of the culture of small pieces of the mantle-wall of *Helix aspersa*, more particularly to obtain aseptic growths In such cultures the amœbocytes wander out of the piece of tissue and become much flattened, but do not form a connective tissue network to such a degree as in non-aseptic culture In older explants, the Golgi apparatus of the amœbocytes breaks up into granules which become scattered through the cells, hence statements concerning the Golgi apparatus, based on evidence obtained from cells in culture, are of doubtful value. There is good evidence that the cells in the tissue cultures of *Helix* divide by amitosis The amœbocytes do not ingest bacteria until the latter have become very numerous. Joyce C Hill contributes (*J Roy Micro Soc*, 54, No. 3, 1934) a useful article on the technique of the culture of the tissue of *Helix* The Hédon-Fleig saline solution, the composition of which is stated, proved to be the most satisfactory, for in this the amœbocytes which emigrated from the mantle wall produced a well-organised connective tissue network By sterilising pieces of tissue, either by exposure to ultra-violet radiation or by soaking in blood, the life of the cultures was much prolonged The amœbocytes were more flattened and did not unite to form a definite network.

Iodised Wraps for Fruit Storage. Mr R. G. Tomkins, of the Low Temperature Research Station, Cambridge, has investigated the possibilities of using iodised coverings for fruit when placed in storage The severity of many fungal diseases of storage is notorious, and the use of germicidal covers would appear to be one of the most obvious methods of control, if the fungicide has no harmful effect on the fruit Initial difficulties seem to have been largely overcome (*J Pomol. and Hort Sci*, 12, No 4, pp 311-320, December, 1934) The iodised wraps are made by treating tissue paper with a definite volume of iodine solution—a covering 25 cm square contains approximately 30 mgm of free iodine Laboratory tests show that storage rots of fruit can be considerably reduced by this kind of wrapping, whilst the appearance and ripening of most varieties is not impaired. Problems for the future include a study of the amounts of iodine absorbed by the fruit, and a more extensive determination of varieties which are harmed by iodine treatment

Cyclones in Mauritius. The cyclone season of 1932–33 in Mauritius and in the neighbouring parts of the South Indian Ocean is described by N. R McCurdy, director of the Royal Alfred Observatory, Mauritius, in Miscellaneous Publication No. 15 of that observatory. This is the sixth of a series of publications dealing exclusively with the cyclone seasons of that region For this year the amount of data available for drawing synoptic charts is greater than at any time previously. There were six cyclones in this season, a smaller number than usual, and fortunately only one of these appears to have been intense. The storm in question appeared on the synoptic charts for March 3-15, 1933, and passed between Mauritius and Madagascar, it followed a very

unusual course, twice approaching Madagascar from the north-east and recurving to the south-east. Several ships were involved in the region around the centre, where winds of hurricane force were encountered with very heavy rain and extremely high seas, and one ship was unfortunate enough to spend some days near the centre, having waited for the storm to pass away to the south-east after the first recurve and being involved in the second recurve, when the rate of travel of the centre was only two miles an hour Another interesting phenomenon was noted in connexion with two storms in February 1933 These formed within a few days of one another and both appeared on the synoptic charts for several successive days. This is regarded as a common occurrence in this region, for three similar cases were described in Miscellaneous Publication No. 14, which describes the cyclone season of 1931–32 One of the remaining cyclones provides an example of the partial break up of a storm on its encountering the high ground in Madagascar The author of these papers concludes that cyclones do not disturb the winds of the cirrus level at Mauritius when their centres are more than two or three hundred miles away.

Heating of Electric Cables exposed to the Sun. The maximum current an electric cable can carry is fixed by the temperature rise of the cable after the current has been flowing so long that the cable has attained a constant temperature It is usual to specify a temperature rise of 50° C above that of the surrounding air If the cable is exposed to direct sunlight a substantial increase of temperature will occur, and this will increase the resistance of the cable and consequently the electric power lost in it The British Electrical Research Association has prepared a report on this subject (*J Inst Elec Eng*, Dec. 1934). The maximum solar radiation in different parts of the world is known approximately, and useful tabular information is given in this report. From this, the temperature rise of a cable of given diameter suspended on a rack can be determined for a given air velocity by means of a factor which varies with the diameter of the cable and with the velocity of the air Practical tests were carried out at London, Milan and Buenos Aires. The maximum temperature was observed and is reached when the sky is clear in about half an hour if the cable is exposed to the sun's radiation between 12 noon and 2 p m summer time Under these conditions, cables of about two inches in diameter may show a temperature rise of 17° C This figure must be deducted from the permissible rise of 50° C. above shade temperature This materially reduces the permissible current the cable can carry. The results obtained abroad are in good agreement with those obtained in England. In an appendix, the theory of the rise of temperature is given The agreement of the experimental results with theory is much more satisfactory for the lead-covered cables than for the armoured cables

An Electric Method for Measuring Young's Modulus. It is well known that a definite relationship exists between the stress and the permeability of iron, steel, nickel and cobalt wires. Joule observed in 1847 that a bar of iron changes its length when magnetised, and forty years later Shelford Bidwell carried out a large number of exact researches in this connexion. He measured the changes of length of wires when placed in a magnetic field both when the wire was loaded and when it was unloaded. Dr. T. F. Wall has developed an interesting electromagnetic method for measuring Young's modulus (*J. Inst Elec Eng*, Dec. 1934; see also NATURE, 132, 351; 1933 and 133, 418; 1934) It is based on the fact that, with magnetisable materials, the magnetic permeability changes with strain When a rod of iron, steel, nickel or certain alloys is placed axially in a solenoid excited by direct current, and the rod is caused to vibrate longitudinally with its natural frequency, the changes of mechanical stress will produce corresponding changes of the magnetic flux in the rod Hence an electromotive force of the same frequency will be induced in a search coil which embraces the magnetised part of the rod The frequency of this E M F is measured by means of oscillograms, and from the density of the metal and this frequency the value of Young's modulus can easily be calculated For the time wave a standard tuning fork was used having a frequency of 500, the vibrations being maintained electrically The results obtained by experiments on iron rods, mild and hard drawn steel wires and nickel rods are given They show that satisfactory results are easily obtained

A Cosmic Ray Meter. A detailed description has been published of a precision recording cosmic ray meter which has been designed by Profs A H Compton and E O Wollan, of the University of Chicago, and R D Bennett, of the Massachusetts Institute of Technology, for securing continuous records of the variation of cosmic rays at a number of widely separated stations (*Rev Sci Inst*, Dec 1934) In order to minimise fluctuations, the ionisation sphere has been made of 19 litres capacity, and is filled with very pure argon at 50 atmospheres pressure It is protected from local radiations by a 17 cm. layer of uniform lead shot, which reduces their effect to about 0·5 per cent of the usual cosmic ray effect The ionisation voltage is provided by a 650 volt dry battery, and the ionisation current is nearly compensated by that produced in a small chamber within the larger by the beta-rays from an adjustable surface of metallic uranium The residue current is indicated by a Lindemann electrometer, the shadow of the needle of which is projected by a compound microscope on a moving strip of bromide paper

Spectra of Giant and Dwarf Stars in the Red. Some interesting luminosity effects, which will serve as very good criteria for distinguishing giants from dwarfs in stars of spectral type *M*, have been discovered by Dr Y. Ohman through a study of representative stars in the orange and red regions of their spectra (*Astrophys. J*, **80**, 171) The instruments used were the 60-in. reflector at Mount Wilson Observatory, with the Cassegrain spectrograph and 18-in camera, giving a dispersion of about 180 A per mm. at 7000 A He found that three bands of CaH at 6389–6382 A., 6921–6903 A., and 7305–7208 A occur conspicuously in the dwarf spectra, but are weak or absent in the giants. These bands first appear (in the dwarf spectra) at type *Mo* and become stronger in later subdivisions, whereas in the giants they are faint throughout. In addition, the spectra of the dwarfs appear smoother than those of giants, on account of the presence of much stronger TiO bands in the latter. The author also confirms Miss Burwell's results for the calcium lines 6162 A., 6122 A., and 6102 A., all of which are very strong in the dwarfs, but faint or invisible in giants.

Chemical Technology at the Imperial College of Science, London

ON January 16, at the invitation of the governing body and the rector, a distinguished company visited the Department of Chemical Technology of the Imperial College of Science and Technology, the occasion providing an opportunity for observing the progress achieved during the past quinquennium

Under the leadership of Prof W A Bone, the Department, which is exclusively of a postgraduate and research character, has continued its policy of pursuing investigations of a fundamental and pioneering character bearing upon what may be termed 'long distance' problems of industry Such work invariably calls for new experimental methods, and a feature of the various apparatus on view was that much of it has been designed in the Department itself and some is unique

The maintenance costs of the Department's extensive research work are naturally heavy, but the support which has always been forthcoming from outside firms and institutions bears ample testimony to the high regard in which its activities are held The chief extramural contributors towards the researches have been the Royal Society (Messel Fund), the Department of Scientific and Industrial Research, the British Iron and Steel Federation, Imperial Chemical Industries Ltd, the Gas Light and Coke Company, the South Metropolitan Gas Company, Messrs Radiation Ltd, Messrs Ferranti Ltd, Messrs Westinghouse Brake and Saxby Signal Co, and Messrs E G Acheson Ltd Altogether, the cost of the research work now amounts to upwards of £9,500 a year, of which approximately 65 per cent is met by special *ad hoc* extramural subscriptions Since its inauguration in 1912, contributions from outside sources towards the research equipment and work of the Department have amounted to more than £60,000 (capital equipment = £15,000), above five-sixths of which has come through Prof Bone

During the afternoon, Prof Bone gave an account of the work of the Department. In subsequent speeches Prof H E Armstrong and Mr H James Yates, chairman of Radiation Ltd, paid a high tribute to it and stressed its scientific and national importance Although Prof Bone will shortly reach the retiring age of sixty-five, they think it would be calamitous if a stringent application of a rule were allowed to interfere with its continuity or with his continued direction of it

Recent advances in the work of the Department, which is divided into sections devoted to fuel technology (including high-pressure gas reactions), electrochemistry and chemical engineering were demonstrated in the various laboratories, and may be summarised as follows —

FUEL TECHNOLOGY

Chemistry of Coal The cost of this work, directed to problems connected with the natural maturing of coal, has been defrayed mainly by grants from the Fuel Research Board It has resulted in (i) new knowledge bearing upon the origin and development of the main 'coking constituents' of bituminous coals, (ii) the discovery not only of the essential 'benzenoid' structure of the main coal substance but also the development thereof throughout the lignin-peat lignite coal-anthracite series

Mechanism of Gaseous Combustion Several investigations have been continued on (i) the combustion of carbonic oxide, (ii) the combustion of hydrocarbons, (iii) flame spectra, etc New evidence has been forthcoming that carbon monoxide burns in two ways, one involving and the other independent of the intervention of steam, also that the initial oxidation product of a gaseous hydrocarbon is the corresponding alcohol as postulated in the hydroxylation theory

High-Pressure Gas Reactions and Explosions The work upon gaseous explosions with which Drs D M Newitt and D T A Townend have been specially associated has been extended to initial pressures of 1,000 atmospheres, the highest yet attempted Nitrogen activation in explosions of carbon monoxide-air media has been shown to reach a maximum at *c* 350 atmospheres, and nearly 6 per cent of nitric oxide to be recoverable from $2CO + 3O_2 + 2N_2$ explosions at 75 atmospheres

Dr Newitt has also developed a new line of work on the pressure oxidation of typical hydrocarbons with the view of elucidating the mechanism of the process and of obtaining large yields of intermediate products A yield of 50 per cent of methyl alcohol has been obtained from methane and 60 per cent of ethyl alcohol from ethane, while toluene has yielded large amounts of benzyl alcohol and benzaldehyde

The high pressure field has also been extended by Dr Townend to the determination of ignition temperatures of paraffin hydrocarbon, etc —air mixtures, with results of great significance both theoretically and in regard to internal combustion problems. Briefly, it has been discovered that the ignition temperatures are located in two widely separated ranges, one usually above 500° C for low pressures and the other below 350° C for high pressures Transference of an ignition temperature to the lower range occurs abruptly at a definite critical pressure, this pressure corresponds with the incidence of 'knock' in an engine at a definite compression ratio

Another centre of interest was an impressive high-pressure apparatus designed by Dr. Newitt for investigations on liquid organic reactions at pressures of 5,000 atmospheres This work, which has been financed by Imperial Chemical Industries Ltd, and is under the joint supervision of Profs Bone and Thorpe, has met with such success that new installations are now in course of erection for pressures between 10,000 and 20,000 atmospheres

Flame Propagation in Gaseous Explosions. This work has consisted mainly of photographic researches, throughout which Mr R P. Fraser has collaborated with Prof Bone and developed the present Fraser high-speed camera of the rotating mirror type whereby detailed records are obtained, capable of measuring flame movements of frequency down to one-millionth of a second Important new knowledge concerning the influence of compression waves, the phenomena associated with 'spin' in detonation and the influence thereon of magnetic and electric fields has been obtained, with the result that a new conception of detonation has been arrived at and is shortly to be published

Blast Furnace Reactions Begun in 1925, under the auspices of the British Iron and Steel Federation, this investigation has also made notable advances, special apparatus having been devised for determining the relative velocities of 'carbon deposition' and 'ore

'reduction' reactions at various temperatures and high gas speeds as met with in blast furnace operations. During the past few years the work, which is carried out by Dr. H. L. Saunders, has thrown such important new light on blast furnace reactions that recently the Federation decided to finance and develop parallel investigations up on actual blast furnace plant. With this end in view, a Committee has been formed, with Prof. Bone as chairman, to organise and carry out this programme of work.

ELECTROCHEMISTRY

Gaseous Combustion in Electric Discharges and Electrical Ignition. Inaugurated in 1925 by Asst. Prof. G. I. Finch, these investigations have been continuously prosecuted, and new light thrown on the combustion of hydrogen and carbon monoxide and on the part played by the hydroxyl radical in such circumstances.

In addition to having established the excitation view of electrical ignition, a notable improvement in the design of electrical ignition systems for mobile internal combustion engines has been achieved. Also as an outcome of work on the analysis of discharge phenomena in ignition, a type of high speed cathode ray oscillograph has been developed which has now been widely adopted in other laboratories.

Electron Diffraction and Heterogeneous Catalysis. It has been established that electrical condition, catalytic activity and structure of surface catalysts are intimately related. Great progress in this field has recently been made possible by the application of the electron diffraction method of structure analysis.

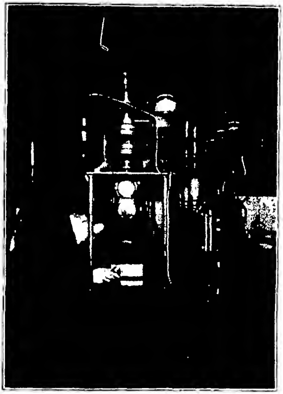

FIG. 1. Electron diffraction camera.

A number of precision cameras designed by Prof. Finch were on view (Fig. 1); other chemical problems being attacked by this new method are (i) corrosion, (ii) electrodeposition, (iii) thermionic and photo-electric emission, (iv) lubrication, (v) properties of colloidal metals, (vi) formation of surface compounds, etc.

CHEMICAL ENGINEERING

The chemical engineering section of the Department suffered a severe loss through the death of Prof. J. W. Hinchley in 1931. Since that time, Asst. Prof. S. G. M. Ure has taken charge of it and is directing work on general problems such as (i) heat transmission, (ii) flow of liquids through granular beds, woven materials, etc., (iii) the distribution of energy in ball mill operations, etc.

During the quinquennium, 98 students, 21 of them from overseas, have passed through the Department; of 78 whose locations are known, 63 have passed into industry, 10 into research or business posts and 5 into academic work.

Lunar Influence on the East Anglian Herring Fishery

FLUCTUATION in the yield from year to year, from month to month, and even from day to day, is one of the outstanding and disconcerting characteristics of all herring fisheries. For thirteen seasons, 1921–1933 inclusive, careful records have been kept of the amount of herrings landed daily at Yarmouth and Lowestoft during the late autumn (October-November) fishery off the East Anglian coast. These figures of daily landings have now been submitted to detailed analysis by the scientific staff of the Ministry of Agriculture and Fisheries, Lowestoft, who find that they reveal a definite monthly rhythm in the catches, the maxima coinciding with the period of full moon*.

When the moon is at full in the first week of October its effect is but slight, but the landings gradually increase as the season advances, to culminate in a peak during the week of November full moon. In these circumstances, it is only the middle and later parts of the season which produce good catches. A full moon occurring in the second week of October produces a pronounced peak in the curve of landings, this maximum being followed by one of approximately equal magnitude in the week of November full moon. Full moon in the third week of October produces a still more pronounced peak for this period, but the corresponding November full moon is considerably less effective. Finally, when the moon is at full during the fourth week of October, it produces the largest peak of all, but the late November moon is accompanied by a rise so slight as to be of little benefit to the fishery.

From these observations it follows that the best prospects for a successful fishery—at any rate from the point of view of production—are found when the October full moon occurs in the second week of the month. When this happens, the combined effects of the October and November moons are greatest, and a period of about five weeks good fishing may be

* Lunar Influence on the East Anglian Herring Fishery. By R. E. Savage and W. C. Hodgson. *Journal du Conseil*, 9, No. 2, 1934, pp. 223-239.

expected A very late October full moon is the least promising of all, for then only one prominent peak occurs in the fishery The period of good fishing is therefore very short, and if it should happen that the activities of the fishing fleet be restricted by adverse weather conditions at this time, the chances of a successful fishery in that season are extremely slight

The occurrence of these peaks in the curves of landings during the weeks of full moon is held to be more than coincidence, and the data certainly appear adequately to support this view The authors are at a loss, however, to suggest an explanation for this correlation between the yield of the East Anglian herring fishery and a phase of the moon This task is made all the more difficult by the fact that the same correlation is not exhibited by the herring fisheries in other localities Either there is no obvious correlation at all between the landings and the moon's phase—as in the Scottish fisheries or the peaks occur during a different phase of the moon—as at North Shields, where the maxima occur during the 'first quarter'

It should be emphasised, however, that failure to find an explanation of the influence exerted by the moon on the great East Anglian fishery in no way detracts from the value of the observations which have demonstrated its existence The authors are therefore to be congratulated upon having fully achieved the two-fold object of their investigations In a notable advance towards the making of more accurate forecasts of fluctuations in the yield of an important fishery, they have succeeded also in adding materially to the sum of our knowledge concerning lunar periodicity in the behaviour of animals

University and Educational Intelligence

CAMBRIDGE —The Vice-Chancellor announces a further gift from Dr G P Bidder, of Trinity College, for the benefit of occupants of the Cambridge table at the Zoological Station in Naples For three years Dr Bidder has made annual payments of 5,000 lire into a Naples bank for the maintenance of occupants of the table during their sojourn in Naples He now offers to deposit in that bank securities which, by the use of principal and interest, will provide 5,000 lire annually for the same purpose, for a further period of ten years The professor of zoology will have discretionary powers over the fund

The Goldsmiths' Company has made a grant of £5,500 for defraying the expenses of an investigation of the alloys of silver, to be carried out in the Metallurgy Laboratory under the guidance of Prof R S Hutton, professor of metallurgy at Cambridge The grant is to be spread over three years

AN American "Educational Review" published as a supplement to *School and Society* of December 1 conveys the impression that school teachers in the United States are to-day very much on the defensive Awakening from a dream of heaven-ordained security, they recognise that they have lost much of the unquestioning popular reverence they and their predecessors enjoyed for generations, and are no longer taken seriously as oracles of civic wisdom If the President's 'new deal' is to provide old-age pensions and unemployment insurance, there will, it is felt, be a danger of these social services being financed in part by encroaching on school budgets The same review comments on the progress of adult education with special reference to an 'alumni education' movement which is peculiar to America Among its manifestations are mentioned a three-day conference at Seattle on present day economic and political problems, in which a thousand alumni of the University of Washington participated, similar conferences of alumni of other universities and an annual two-week Institute of Public Affairs organised by the University of Virginia

Science News a Century Ago

The Entomological Society

The anniversary meeting of the Entomological Society was held on January 26, 1835, J. G Children, Sec R S , the president, being in the chair After the passing of the minutes and accounts, the president delivered an address in the course of which he congratulated the Society on the progress of entomology and the favourable report which had just been read, while the secretary followed with a sketch of the progress of the science at home and abroad The officers elected for 1835 were *President*, Rev F W Hope , *Treasurer*, Mr Yarrell , *Curator*, Mr Pickering , and *Secretary*, Mr Westwood

Royal College of Physicians

The president of the Royal College of Physicians from 1820 until 1844 was Sir Henry Halford (1766–1844), who was physician in turn to George IV, William IV and Queen Victoria On January 26, 1835, according to *The Times*, the evening meetings of the Society were commenced at the College in Pall Mall Sir Henry Halford was in the chair and the meeting was attended by about seven hundred persons including many distinguished statesmen, lawyers and others The meeting began at 9 o'clock and the company dispersed at 11 o'clock The president, said *The Times*, read a very interesting paper containing some observations on the treatment adopted by medical men from a very early period, in the care of various complaints, and related many amusing anecdotes of the remedies they applied He described the different complaints which terminated the lives of the monarchs who governed Great Britain, and also explained the circumstances attending the deaths of Addison, Dryden, Dean Swift and other distinguished characters

Steam Navigation upon the Danube

Under the above heading, the *Athenaeum* on January 31, 1835, said . "Very gratifying accounts have recently been received of the progress of steam navigation upon this noble river. Under the auspices of the Austrian government, the whole region from Presburg to the Black Sea, and even to Constantinople, a distance of fifteen hundred miles, has lately been opened to the influence of steam This project was first undertaken by Count Czechengi, a Hungarian nobleman of great fortune and very enlightened mind, who in quest of mechanical information, has made several journies to this country Unlike the majority of the Hungarian nobles the Count has exhibited the most enthusiastic devotion to the improvement of his country, by the introduction of the useful arts, and his operations for improving the navigation of the Danube have been upon a scale so vast, as to entitle him to the appellation of the Bridgewater of the German States . ."

GENEVA

Society of Physics and Natural History, November 15. KURT MEYER: Contribution to the theory of narcosis. The author by his experiments gives support to the lipoid theory of narcosis. E. BRINER, E. ROKAKIS and B. SUSZ: Researches on the oxidation of the nitrogen oxides in the presence of ozone. M. GYSIN: The basic igneous rocks of the Haute Lufira (Belgian Congo). In the Haute Lufira basin (Katanga) numerous outcrops of uralitised diabases have been observed, containing a blue soda amphibole and a little dipyre. The blue amphibole forms borders round the uralite regions; the dipyre occurs as small grains mixed with the products of the saussuritisation of the plagioclases. The uralitisation, the formation of blue amphibole and the scapolitisation can be attributed to the action of perimagmatic or apo magmatic mineralised solutions on the diabases. D. ZIMMET: A practical sphygmograph for man and animals.

MELBOURNE

Royal Society of Victoria, November 8. KATHLEEN M. CROOKS: (1) The cultural and cytological characteristics of a new species of *Mycogala*. While isolating several fungi from Jarrah (*Eucalyptus marginata*) timber a new species of *Mycogala*, *M. marginata*, was obtained. There are two types of asexual spores: (*a*) chlamydospores, spherical in shape and dark brown in colour with a thick wall when mature, and ranging from 6 to 18 μ in diameter; (*b*) oidea, formed by the transformation of aerial branches into cylindrical, hyaline elements which again break up into smaller segments one or more septate. Perithecia are abundantly developed. The perithecium initial is a coiled septate hypha—the ascogonium composed of segments at first multinucleate, but later becoming uni-nucleate. An antheridium is not developed. From the ascogonial coil ascogenous hyphæ arise. These branches are rather irregular and recurved at the tip. The ripe asci contain eight spherical hyaline ascospores, 2–4.5 μ in diameter. (2) A powdery mildew of *Boronia megastigma*.—In September and October 1933, *Boronia* growing at Healesville was found to be diseased. The disease was a 'powdery mildew' caused by a species of *Oidium*. The fungus attacked the petals while the stem and leaves appeared quite healthy. From the vegetative mycelium, aerial branches arose and at the apices of these hyphæ, oidia were contracted. The oidia were ovoid in shape and had an average size of 28 μ × 13 μ and a range of 19–38 μ × 11–18 μ. In the family Rutaceae to which *Boronia* belongs, there are few members which have been attacked by *Oidium* species, but the characteristics of the form on *Boronia* do not agree with any of those previously described. Hence it is proposed to give the fungus in question the specific name *Oidium boroniae*. ILMA G. BALFE: Sclerote-forming fungi causing disease in *Matthiola*, *Primula* and *Delphinium* in Victoria. *Rhizoctonia solani*, Kuhn, is recorded as causing 'damping off' of *Matthiola incana* seedlings in Victoria. *Sclerotinia minor*, Jagg., is recorded as causing a collar rot of *Primula malacoides* in Victoria. *Corticium centrifugum* is recorded as causing a collar rot of delphiniums in Victoria. A description of the pathogen in culture is given, and comparisons are made between the strain isolated from *Delphinium*, Wolf's strain of *Corticum centrifugum* and Whetzel's strain of *Sclerotium Delphinii*, Wolch. EILEEN E. FISHER: 'Sooty mould' of the tree fern, *Dicksonia*. A dense black film on the fronds of a *Dicksonia* plant growing in a fernery at Doncaster, 11 miles east-north east of Melbourne, is due entirely to the fungus *Teichospora salicina* (Mont.), Gau.

Scientific Aspects of Housing Problems

THE fundamental scientific problems of the building industry which underlie the housing question were touched upon by Dr Stradling in a lecture on "Physics in the Building Industry" at the end of 1933, and again by Sir Harry McGowan in the Messel Memorial Lecture to the Society of Chemical Industry at Cardiff They have also been indicated by Prof Julian Huxley in his "Scientific Research and Social Problems" and in much greater detail, so far as the United States of America are concerned, by Mr A F Bemis in "The Economics of Shelter", the second of three volumes in a series "The Evolving House"

Nothing corresponding with the latter study has hitherto appeared in Great Britain, but a report entitled "Housing England", which has now been produced by the Industries Group of Political and Economic Planning (PEP), 16 Queen Anne's Gate, S W 1, ably fills this gap and is an important contribution to the discussion of the housing question which deserves close consideration by the scientific worker If studied in conjunction with the housing statistics of the Census of 1931 just available, it will help to create a more scientific, more critical and more constructive attitude towards the problems of housing and of the building industry

Although a comparatively small section of the report is devoted to actual research problems, this attitude supplies its outstanding characteristic It recognises from the start that any sound solution of the housing problem must provide for reconstruction of the building and building materials industry, overhaul of building regulations and the setting up of national standards The discussion accordingly ranges over wide fields of industrial and technical as well as of economic and social questions

The core of the present housing problem in Great Britain is that of supplying suitable accommodation at rents within the means of the lower-paid workers of the community The final report of the National Housing Committee stated that this represented the provision during the next ten years of at least a further million houses to let at rents of not more than 10s per week The present report reaches essentially the same conclusion, estimating that a minimum of 200,000 new houses a year is required for the next seven years, of which half must be available at rents averaging 10s. per week

Leaving on one side the discussion of the political and financial aspects of this question, which the report suggests might be dealt with by means of a national housing company and a national building company, attention is directed to the unjustifiable variations in building costs throughout the country of the more or less standard three-bedroom non-parlour house Technical and economic research on a comprehensive scale is essential for the attack on building costs While such a research programme is properly the function of the building industry as a whole, the industry has not yet developed a collective organisation capable of undertaking the work Accordingly the report regards it as essential that the Government should initiate a centralised housing research organisation to co-ordinate existing efforts so far as possible through existing organisations

This is one of the most important recommendations of the report, and the section entitled "Research and Statistics" on which it is based, will be read with close interest by all scientific workers. At present even market research in the building industry is remarkably casual and incomplete, and largely in the hands of advertising agents Vital information on proprietary and non-proprietary materials is unobtainable or obtained with difficulty owing to the law of libel Lack of knowledge about building regulations, which vary from district to district, hampers the operations of building concerns outside their own immediate area The possibilities of economics dependent upon improved management technique, such as the Taylor or the Bedaux systems, and the whole field of industrial psychology, have scarcely been considered or explored by the building industry. Much of the existing scientific work is not applied so quickly as it should be because its results either do not receive adequate publicity or are published in unsuitable form

At the present time, there appears to be almost unlimited scope for the improvement of the facilities for the exchange and co-ordination of information on building progress, building technique, trade names and catalogues, co-operation between libraries and the like Such work inevitably tends, moreover, to overcome one of the difficulties in the way of introducing new methods and the obstacles which the lack of scientific personnel presents to the practical application of research One of the functions of such a central authority might well be the co-ordination of information on training facilities, the type of instruction required, openings, etc

This economic and statistical research is intimately related with the technical research work discussed in the same section of the report The scarcity of men with a scientific training on the contracting side of the industry is in extraordinary contrast with the executive branches of engineering or even cotton, and presents a very serious obstacle to progress The expenditure on research by the industry itself is noticeably smaller in proportion to Government expenditure than in other trades, but the wide scope of the industry is one of the reasons why scientific research has made so little headway In addition, research of fundamental importance to the industry is being carried out by other industries, though rather from the point of view of the manufacturer than from that of the consumer Special stress is laid upon the necessity for adequate research from the latter point of view, on the need for full-scale experiments and on the importance of adequate financial support for the Building Research Station

The most important criticisms advanced of existing research organisations are the lack of direct co-operation in direction, and their inability in a non-scientifically minded industry to get the results of their work accepted by the industry The danger of research financed by or carried out mainly for proprietary material interests is also stressed, as is the need for an authority which would facilitate experiment with new systems of construction

One of the chief obstacles to such experiment lies in the chaotic legislative position affecting building and the building industry, particularly the restrictive and antiquated regulations which, in effect, limit the rate of introduction of new materials and new methods Despite the attention directed to this important factor by the first report of the Council for Research on Housing Construction ("Slum Clearance and Rehousing", P. S King and Son, Ltd., Great Smith Street, S W 1; 1934), which asserted that the diversity and obsolescence of building regulations is a principal obstacle to progress and recommended the amendment and more enlightened administration of the system, as well as a more flexible system of by-laws, insufficient attention has yet been given to this factor

Examples quoted in the report of obstacles to the introduction of improved lead piping, fire-proofing practice and the like indicate the absurdity of the

present position Here, as elsewhere, there is to be found a plethora of evidence that the statement quoted by Mr Bemis from a leading American engineering publication is equally valid in Great Britain "The average house to-day is a shoddy affair, of high first cost, and soon reduced to a condition requiring constant maintenance, it is built as it was a great many years ago, by hand methods, with every piece cut in the field by men whose horizon is limited to the locality in which they live, whose training makes them impervious to the adaptation of new methods, whose financial capacity does not permit of modern research or study and who themselves are the victims of profiteering material dealers"

If the report produced by Political and Economic Planning reveals very clearly the immense difficulties in the way of a really scientific housing policy, and in placing building and the building industry on a satisfactory scientific basis, it is far from being a depressing document Its lucid and constructive criticism and pertinent recommendations do not merely point the way forward and assist in the clarification of public opinion on this important matter They also reveal the wide field which here confronts the scientific worker, both as such and as a citizen, to secure that public policy and action are determined by definitely ascertained facts and not by archaic tradition or prejudice

Reviews

Early East Africans

The Stone Age Races of Kenya By Dr L S B. Leakey With Appendices by T W. P Lawrence, Sir Grafton Elliot-Smith, Sir F Colyer, L S B Leakey Pp xii+150+82 plates (London. Oxford University Press, 1935) 38s net

DR LEAKEY led his first archæological expedition to East Africa in 1926, his second in 1928, and his third in 1931 In this imposing memoir, he gives an account of the human remains found on all three expeditions Rich as were the discoveries made in the first and second expeditions, they were thrown completely in the shade by the outstanding importance of those made during the third expedition.

Dr Leakey's third expedition began by a visit to the site of the discovery of Oldoway man in Tanganyika Territory In the Oldoway district the examination of the grave site was a minor matter, for it was in this area that Dr. Leakey discovered a sequence of deposits bearing evidence of the presence of man in East Africa from the earliest Pleistocene times onwards, and by early Pleistocene Dr. Leakey means what most geologists call late Pliocene He speaks of the 'culture' represented by the implements in the oldest deposit as Oldowan—a crude and very early form of hand-axe. Overlying deposits reveal this early type of stone axe in the process of being transformed into the true Chellean and later into the Acheulean form of *coup-de-poing*

In Tanganyika, Dr. Leakey found nothing of the men responsible for the early hand-axe industry, but early in 1932 he moved his expedition to that part of Kenya Colony which extends to Kavirondo Bay, on the eastern shore of Lake Victoria, and had his search crowned with success almost immediately The land into which he came was made up, just as at Oldoway, of deposits laid down in the Early and Middle Pleistocene periods ; only the fauna at Kanam—the site of the most important discovery—was rather of an earlier date than the oldest at Oldoway There were the same crude stone implements in the basal deposits at Kanam as at Oldoway

Very soon after its arrival on the eastern shore of Lake Victoria, the expedition had the fortune to find at Kanam a fossil fragment near the base of the Pleistocene deposits This fragment represents the front part of the lower jaw of one of the earliest human beings known to us Never, perhaps, was a more puzzling piece placed in the hands of a student of fossil man. That it is human and that it is very ancient there can be no doubt But by a very strange coincidence, the chin of this representative of early humanity was the seat of a bony tumour of an exceedingly rare kind. The tumour, which grew from the deep aspect of the lower jaw, just behind the chin, has spread over and obscured the normal features of this region Enough remains, however, to make quite certain that in dimensions and in its features, the chin region of this early being was shaped as in primitive types of living humanity—such as the aborigines of Australia Dr Leakey describes the Kanam man as having "a very pronounced mental prominence". Far from being "very pronounced" the Kanam "mental prominence" or chin represents a low or early stage of chin development.

Dr Leakey does not hesitate to infer that the rest of the Kanam man will prove to be in keeping with the fragment of his jaw, and regards him as the ancestor of modern races of mankind—*Homo*

sapiens This may prove to be the case, but it may not The fragment of lower jaw, which is of the same age as *Pithecanthropus*, and which Dr. Dubois attributes to *Pithecanthropus*, has a human chin region, if Dr Dubois had merely found this fragment, he would have presumed that *Pithecanthropus* was an early representative of *Homo sapiens*, as indeed it may prove to be The lower jaw of some of the Peking fossil men (*Sinanthropus*) show an incipient development of the human chin If Sir Arthur Smith Woodward had been given only the chin region of Piltdown man, he would certainly have inferred that a Pleistocene anthropoid ape had been discovered in England Kanam man, when Dr Leakey discovers him, may be quite unlike his anticipation, for we can place no great reliance on the chin as a clue to the structure of the rest of the body

Dr Leakey does not consider the Kanam fragment in connexion with the most important of all fossil Africans known to us, namely, Rhodesian man The size and shape of the Kanam premolar teeth, the flatness of their worn surface and the massiveness of the chin region (Dr Leakey estimates that the height of the symphyseal region was 42 mm) indicate just such a lower jaw as might be postulated for Rhodesian man

It is said that Dr Dubois went to Java in 1888 to find the 'missing link', he found *Pithecanthropus* Dr. Leakey, in March 1932, went to the Kavirondo country to find the fossil ancestor of modern man He not only discovered the fossil fragment of Kanam man but also at a neighbouring site—Kanjera—found fossil fragments of four other skulls The Kanjera people, however, are later than the Kanam man They fall at that phase of the Mid-Pleistocene when hand-axes had reached their full Chellean development Two of the Kanjera skulls have been reconstructed by Dr Leakey They represent big-headed and big-brained people Their heads were long and narrow Dr Leakey claims that the Kanjera people are by far the earliest representative of true modern man that has been discovered so far That is so, but there are certain very important characters of these fossil skulls which Dr Leakey passes over without mention and yet which, in the opinion of the reviewer, are of the utmost importance for racial recognition Those points are the flatness of the glabellar and interorbital regions at the root of the nose, and the form of the external angular processes of the forehead These are features of the Kanjera skulls and are characters of the Negro race So, too, are their 'infantile' traits, on which Dr Leakey rightly lays emphasis. More than in any race, the Negro tends to retain fœtal and infantile stages in development and growth, as we see in the tendency of this race to throw dwarf forms—such as the Bushman and Congo pygmies. Far from being marked by "generalised characters" as Dr Leakey assumes, the Kanjera people are already endowed with features which definitely assign them to the African or Negro stock Indeed, Dr Leakey's discovery is one of the utmost importance to anthropologists, for it reveals for the first time the differentiation of a modern race of humanity in Mid-Pleistocene times The great enigma, the origin of the modern races of mankind, is brought a big step towards solution We are to find that "parallel or independent evolution" is to play a large part in the differentiation of the modern races of mankind

The other races discovered by Dr Leakey, representing the inhabitants of East Africa in Late Pleistocene and in the Early Post-Pleistocene times, need not detain us long A large part of the present work is devoted to them One is impressed by the prevalence in all these periods by a tall, long-headed, big-brained, heavy-faced type of man It is a type which can still be recognised amongst the native peoples of East Africa and in the upper watershed of the Nile It is a Hamitic or Negroid type, certainly not a pure Negro form Measurements of their bones and drawings of their skulls are given to an extent which will satisfy the most exacting of readers.

Beyond a doubt the discoveries which Dr Leakey has made, and to which the book under review is devoted, take a place among the major events in the calendar of all anthropologists No one can now discuss the rise of humanity and the evolution of early 'cultures' without taking Dr Leakey's discoveries in East Africa into consideration Nor has the work of anyone been given a finer setting than the Oxford University Press has given to "The Stone Age Races of Kenya" That makes it all the more regrettable that many of the plates show crude draughtsmanship and much of the text evidence of hurried composition.

ARTHUR KEITH

The R.S.P.C.A.

A Century of Work for Animals the History of the R S P C A, 1824–1934 By Edward G. Fairholme and Wellesley Pain. Second edition Pp xx+308+8 plates (London · John Murray, 1934.) 2s. 6d

THE century's work of the Royal Society for the Prevention of Cruelty to Animals was published in 1924, and now a second edition carries that history on through the succeeding decade. Both this and the analogous Society in respect to children have done notable work in directing the attention of the public to cruelty in whatever form they found it. They have used the

law courts, the decisions of which attract the public and are educative in themselves The times too have been favourable, for education became compulsory in the latter half of last century and has been increasingly conducted by men of broad outlook and knowledge With the spread of scientific knowledge, it is difficult to conceive of avoidable cruelty now being countenanced by educated men, since all such would naturally be imbued with the ideas of evolution and with the close relationship, even ancestral, that this implies between man and beast

The successive 'ages' of amphibians, reptiles and mammals were established, with the implied replacement of older forms by descendants better adapted to cope with the difficulties of life Often the establishment of a new age was a cruel process, for Nature's unalterable laws are often cruel This, however, is no longer the age of mammals but the age of man, and this age has not been established without cruelty not only to mammals but also to less intelligent races of man Now man is becoming highly mechanised With civilisation his whole life is artificial However, with this there would seem to be a development of a humane instinct for Nature, seen practically in the growth of Nature reserves and national parks Unfortunately, scarcely one of these can be left to itself, since a few animals and plants in each soon dominate to the exclusion of weaker types Man has to rule, but fortunately the instincts for civilisation and kindness seem firmly coupled

From the history before us we gain the impression that the Society's activity has been largely directed to securing penalties for inhumanity and inventing more humane methods of necessary slaughter, together with such propaganda as was desirable to secure these and to make detestable the needless destruction of wild creatures To-day, any case of inhumanity excites detestation, and such cases can be increasingly left to the community In the present story no chapter deals with future work, yet the Society must be aware that it cannot rest on its laurels and still flourish Is not there a wide field before it in encouraging the study both of the feeding and of the diseases of domestic animals, thereby ultimately alleviating their lives ? Is not the development of veterinary science to a position akin to that of medicine increasingly to be desired ? How far can Government-managed laboratories be expected to concentrate on our pets ? Assuredly the funds would be forthcoming if the Society would establish its own research institute in the interests of such 'low priced' beasts.

Furthermore, while for forty years we have ceased to mutilate our dogs for the show bench, are any of our methods for the minor beasts causing them pain ? What are our aims when we breed these in captivity ? Are we breeding for stamina and health and intelligence, three factors which apparently mean happiness to their possessors ? Or is our aim merely to secure the money of lovers of the bizarre, forgetting that monstrous developments in any form are frequently accompanied by loss of stamina and brain ? Not to consider the nature of any pet is cruel and inhumane, and surely a pet must not be regarded as the inane doll of its owner.

The Society's position as to vivisection is that it "deprecates all experiments on animals which cause pain" This is exactly the position of scientific men of all shades of thought, but they recognise that their first duty is to alleviate the sufferings of their children, even if they require very occasionally to learn how to do so at the expense of animals In other words, they follow the law of Nature which to-day has assigned pride of place to man To judge by its précis of evidence before the Royal Commission of 1907, the Society was scarcely fair It did not distinguish between painless inoculations and experimental operations, or between those of Governmental and private, usually university or hospital, laboratories Without any new Act of Parliament, so far as we can judge, every change asked for by the Society or the Commission has been effected administratively. There is an unbribable inspectorate of the highest class, the most rigid control and a universal employment of anæsthetics No operations are possible except for definite and approved ends ; and to crown all, there is the universal opinion of the scientific world deprecating cruelty and any attempt to evade the Act Indeed, the British faculty for compromise would appear to have reconciled desirable sentiment with practical necessities, and the Society would do well to recognise this

Bessel Functions for Engineers

Bessel Functions for Engineers By Dr N. W McLachlan (Oxford Engineering Science Series) Pp xii+192 (Oxford Clarendon Press ; London Oxford University Press, 1934) 15*s* net

THE value of Dr McLachlan's book to engineer users of Bessel functions will depend on the kind of engineer who refers to it. Probably the electrical or acoustical engineer will be well pleased and all other kinds relatively disappointed The preface makes the contents quite clear, but had the book been called "Bessel Functions for Wireless Engineers" a more correct impression of its contents would have been given.

A general indication of the problems selected

for consideration by the author will show the scope of the book; he deals with loud-speaker horns, electrical transmission lines, alternating current density and skin effect in wires, electric furnaces of eddy current type, etc. Another group of subjects covers the vibration of stretched membranes, the lateral vibrations of a conical bar and the 'virtual mass' added to a body when accelerating through a fluid. On these subjects the book is adequately self-contained.

The general pattern of the chapters is a beginning of theory and an ending of examples. The latter are very numerous—some six hundred in all. The author's statement that the book has been used with success for a course of lectures to practising engineers can readily be accepted as true, but the question still remains as to what the author meant by the expression "for engineers". Probably Dr. McLachlan had in mind the textbook by G. N. Watson as one suitable for mathematicians rather than engineers since a considerable analytical skill is required to extract working formulæ from that treatise. On the other hand, there is the book by Gray, Mathews and MacRobert, and we should hesitate to describe that as unsuitable for engineers; in fact, almost the whole of the theoretical part of Dr. McLachlan's book is to be found in the same form in MacRobert's, but in the latter there is additional matter with engineering applications. Such extra matter covers the addition theorems and the contour integrals which Dr. McLachlan deliberately leaves out. Such integrals are not obtrusive in MacRobert's work and the general arrangement of the theoretical part in that work may be preferred to that of the new volume. It may be that familiarity with the older work has produced a bias in its favour.

It is pleasing to find the author stressing his belief that "it is rather hazardous to solve practical problems with a book in one hand and a pen in the other without a proper knowledge of the processes involved", and within its admitted limitations the whole book satisfies the criterion laid down by giving adequate discussion of the theory behind the applications.

The book ends with certain tables of Bessel functions comparable in value to the tables in Jahnke and Emde and much less accurate than those of Watson and MacRobert. Perhaps a textbook on Bessel functions is no longer a suitable place for it, but a comprehensive collection—not limited to four significant figures—would be welcomed by some engineers. Lack of even a moderately complete set of tables seems to detract appreciably from the practical value of Dr. McLachlan's book.

L. B.

Short Notices

Neuroanatomy: a Guide for the Study of the Form and Internal Structure of the Brain and Spinal Cord. By Prof. J. H. Globus. Sixth edition, revised and enlarged. Pp. xv+240 (53 plates). (London: Baillière, Tindall and Cox, 1934.) 16s.

TEXTBOOKS of neuroanatomy are rather apt to become redundant. "Neuroanatomy" by Prof. J. H. Globus was first published in 1915, and we now have the sixth edition. This edition has a method of dissection, and we can rest assured that any student who follows these dissections carefully and discusses the questions asked at the end of each 'assignment' will have a knowledge of the anatomy of the nervous system which will be enduring and at the same time exhaustive.

The book is divided into two parts, the first dealing with the description of the various parts of the brain together with the directions for dissection, etc. The second part consists of the plates, fifty-three in number; these can be detached and after completion by the student replaced in the book by adhesive paper. There are thirty-six figures in part one, all of which are original. The descriptions are extremely lucid and well done, and we congratulate the author on making what is really a very dry and difficult subject to most students into a fascinating and most interesting study.

There is an excellent index.

Nervous Breakdown: its Cause and Cure. By Dr. W. B. Wolfe. Pp. xv+260. (London: George Routledge and Sons, Ltd., 1934.) 7s. 6d. net.

THE question of the nervous breakdown is always with us, and few people realise the amount of time and money lost to the nation each year by people who have personal problems to solve and difficulties to meet that are too much for them. How many people lose heart in the struggle in unhappy homes with individuals they have learnt to hate and end it all in the river or what is nowadays much more comfortable—the gas stove. It is so easy, such a relief from torment. Fifteen people commit suicide in England every day. How many try but do not succeed! and how many consider it, and say they have not the pluck to do it? To all these struggling individuals this book is addressed, and there is no doubt that it will be a great help, but how many are likely to read it? Few, we fear.

The author has shown himself a deep student of human nature and its weaknesses. How many of us are striving to save our 'face'! In his "plain words to parents" there is much worldly wisdom. To learn a funny story and tell it until you make someone laugh is good advice, but does not mean carrying *Punch* under your arm every day as one man used to do until he became an unsufferable bore!

(1) *The Selection of Colour Workers : being a Research into the Practical Methods of measuring the ability to discriminate Fine Shades of Colour* Begun by A. M Hudson Davies and A. Stephenson Completed and described by W. O'D Pierce Edited and with a Preface and a Chapter by Charles S Myers. Pp xi + 134 5s net

(2) *The Case for Vocational Guidance : Three Lectures given under the Heath Clark Bequest to the National Institute of Industrial Psychology* By Angus Macrae Pp vii + 92 3s 6d net

(London Sir Isaac Pitman and Sons, Ltd, 1934)

BOTH these books well exemplify the pioneer research work which is being carried out under the auspices of the National Institute of Industrial Psychology.

(1) The first arose out of a request by a firm of colour printers for a test which would enable them to make selections from their employees for the more responsible positions in the firm From this beginning there followed a prolonged psychological inquiry, resulting in the practical test of colour discrimination here described by members of the staff of the Institute The test has already been proved to have high value in the selection of competent colour workers

(2) The second book is general in character, and relates to the great problem of vocational guidance for boys and girls leaving school As the author sadly remarks, many young people in these days are less concerned with the difficulty of choosing suitable work than with the difficulty of finding work at all Even so, there are many even now who have some choice in the matter, and this short book by Mr Macrae puts the case for systematic guidance in making that choice wisely He does not enter upon the details of the technique of the methods employed by the vocational psychologist He points the way, and supplies bibliographical information for those readers who wish to pursue the subject further. In so doing he has performed a useful service.

Anleitung zu optischen Untersuchungen mit dem Polarisationsmikroskop. Von F Rinne und M Berek Pp viii + 279. (Leipzig : Max Jänecke, 1934) 11 60 gold marks

THIS book appears after the death, on March 12, 1933, of one of the authors, Prof F Rinne The task of completing the work and seeing the manuscript through the press fell to the lot of Prof Berek of Wetzlar, who was taking part in the revision of an earlier book, "Einführung in die kristallographisches Formenlehre", by Prof Rinne, with the idea of strengthening the optical treatment of the subject.

The name of Prof Berek will, of course, be a guarantee that the optical aspect of the subject is well and adequately discussed, and although doubtless some initial study of physical optics would be necessary for a beginner before taking up the volume (the introductory sections are brief in character), the book appears to be a very useful and systematic review of the application of microscopy to the qualitative and quantitative investigation and identification of crystalline substances.

Some of the later sections, on luminescence and on the application of the microphotometer for the measurement of absorption, may be mentioned as bringing the matter well up to date, and Prof. Berek's association with the firm of Leitz will naturally indicate good descriptions of modern resources in apparatus The book is profusely illustrated with diagrams and photographs

Venereal Disease its Prevention, Symptoms and Treatment By Hugh Wansey Bayly Fifth edition Pp xv + 260 + 3 plates (London Chapman and Hall, Ltd, 1934) 10s. 6d. net

THE first edition of Dr Bayly's "Venereal Disease" appeared in 1919 This is the fifth edition, and it is an improvement on the other editions The author very wisely, we think, points out that a number of competent judges consider that there is a definite increase in the prevalence of neurosyphilis, and not a reduction, as so many hoped there would be Probably the wish was father to the thought It is probable that the ideal treatment for general paralysis is tryparsamide followed by malaria or some other pyrexial treatment and then tryparsamide again The last word on the various fever and arsenical treatments of general paralysis has by no means been said, and in twenty years' time we may find all these present treatments scrapped From the descriptions given, it is rather difficult to see how a differential diagnosis between cerebral syphilis and general paralysis can be made

The book is extremely well laid out and the illustrations and directions for treatment are very good The book is also not too long and diffuse, and is one that we recommend

Handbuch der Spektroscopie. Von Prof H. Kayser und Prof H Konen Band 7. Dritte und letzte Lieferung Pp 751–1473 + xiv. (Leipzig S. Hirzel, 1934) 80 gold marks

THE colossal task of bringing Kayser's standard "Handbuch der Spektroscopie" up to date, which has been undertaken with the assistance of Prof. Konen and other collaborators, is carried forward another stage by the appearance of this, the third and concluding part of vol 7 The publication contains data, complete to July 10, 1933, for the fourteen elements (as usual, in alphabetical order of chemical symbols) from Il to Nb, and the fact that, on the average, fifty pages are required for each element indicates to some extent the imperative need of the practising spectroscopist for such a collection as this With this part are included also an index and an introductory note to the seventh volume.

The general plan and characteristics of the work are so well known that comment is unnecessary : it is sufficient to say that in every respect this issue appears to conform with previous ones The publishers announce that vol. 7, containing 1473 pages and dealing with the elements from argon to niobium, can now be obtained complete at a cost of 132 20 gold marks (bound, 141 gold marks).

Ecology and Rubber-Growing

BROADLY speaking, there are two ways of 'growing' plants useful to man. The first and most obvious is to treat the plant as an agricultural crop, that is, to clear the ground of existing vegetation, prepare it by digging, ploughing, or other treatment, and then to sow or plant the crop, which is kept 'clean weeded'. The second is employed where large tracts of natural vegetation are useful as a whole, or contain useful species, as with pasture grasslands or forest. Here the primary attention required is to see that the regime of exploitation, by the grazing of stock or by felling, is not such as to impoverish the vegetation as a whole, or to favour useless at the expense of useful species. Besides regulating the regime, active interference to these ends is sometimes required.

There are, of course, many crops which are managed by some intermediate method. Thus the primary crop may be sown or planted in the first instance, but other plants may be introduced or allowed to come naturally into the spaces between the crop plants because they are useful in assisting the growth of the main crop plant or in protecting the soil surface. A well-known example is the planting of 'nurse' trees or shrubs, which are eventually removed, between the seedlings or saplings of a young plantation. In all such cases we begin to approach the conditions of natural vegetation, in which more than one species grow in association and the different species present act and react on one another, either favourably, or unfavourably by direct competition for light, food or water. The study of such interactions under the given conditions of habitat is the most important part of what is called plant ecology.

The history of the great rubber-growing industry of the eastern tropics provides an interesting example of a change from the first towards the second of the two methods of treatment. When the first seedlings of *Hevea brasiliensis* were planted commercially in Malaya towards the end of last century, and for several years afterwards, when extremely remunerative results were being obtained, the universal practice, or at any rate the universal ideal, was to keep the plantation 'clean-weeded', and with the cheap labour obtainable this was quite possible on the more successful estates. But after a time it became increasingly clear that the practice was not everywhere desirable. Especially on sloping ground, the bare soil was exposed to erosion by the torrential rains and great damage was done; the soil also deteriorated by the direct action of sun and rain; it often became compact and hard, a result to which the constant trampling of the coolies contributed; and the absence of humus led to its impoverishment in essential mineral food stuffs. Consequently the trees began to suffer and their supply of latex to fall off. 'Clean weeding' began to lose its prestige; and this process was notably aided because, when the slump followed the boom, it was no longer so easy to find the necessary labour. 'Ground cover' began to be planted, at first leguminous plants, which, besides protecting the soil, were expected to increase its combined nitrogen. The legumes, however, were not very successful, largely because their growth under the rubber trees was unsatisfactory.

Then it occurred to someone to try the effect of allowing the natural 'weeds' of the forest to enter and colonise the plantations, which, of course, they had always been trying to do. The results were in many cases beneficial, and the practice became generally adopted. Now, in certain circles, the pendulum has swung to the other extreme, and it is even suggested that a rubber plantation should be treated like a self-regenerating natural forest, with its complex 'stories' of vegetation, and the rubber trees allowed to provide their own successors by sowing their own seed spontaneously! This extreme 'forestry method' of rubber cultivation is far from being generally supported. It is not, for example, the policy of the Rubber Research Institute, though the necessity of 'ground cover' in most cases is recognised. It is obviously true that much more experience is required before we can decide on the relative advantages of such a method of renewing plantations as compared with the established planting and 'budding'.

In a pamphlet recently published, Mr Haines* gives, on the whole, a very fair and interesting review of the situation. He is in favour of what may be described as 'controlled natural ground cover'. Wild plants are allowed to come in, but discriminatingly, and when they become too luxuriant they are to be 'slashed' or otherwise kept down. Different species play different parts under different conditions, and it is impossible to lay down hard and fast rules that some of the natural colonists are 'good' and others 'bad'. All this is just what the ecologist would expect.

One remark of the author (p 8) is very curious. "Practical planters are . . . advised to *study competition* as evidenced in the development in their fields, and to let Latin names and fine botanical distinctions take second place. Accurate

* Rubber Research Institute of Malaya. Planting Manual No. 6: The Uses and Control of Natural Undergrowth on Rubber Estates. By W. B. Haines. Pp. iii+23+20 plates. (Kuala Lumpur: Rubber Research Institute of Malaya, 1934.) 1 dollar.

naming of plants must always be helpful in assembling and disseminating information, but a very general classification on obvious features like the rate of growth, habit of growth, both above and below ground, texture of tissues and similar factors is quite adequate for the purpose in hand." But how on earth is a "practical planter", or anyone else, to "study competition" when he does not know the names of the competing species? Also how will a "very general classification" of the kind described help him here? It is obvious enough that it does not matter what language the names belong to—Latin, English or Malay—(though the scientific names have well-known advantages), provided the same name is always used for the same species and for that species alone, but names in some language are quite indispensable The planter *must* learn the names of the important species on his estate (or give them names of his own) before he can advance a single step in studying competition or increasing his knowledge in any way of what is going on in his plantations, once he lets in the native plants Naturally, it is not necessary for him to acquire an exhaustive knowledge of the whole flora When he has learned to distinguish the important species, then he can most usefully pay attention to their characters and behaviour under different conditions

This, of course, is nothing but ecology, and we very much regret to see that, though Mr Haines himself admits (p 1) that "many of the problems which arise regarding natural covers are ecological", Mr B J Eaton in his foreword summarises "the advantages of natural covers" solely in relation to their effect on soil, and writes that "for a study of this aspect of the problem the employment of a Forester or of a Plant Ecologist, as has been suggested in some quarters, is not essential" Well, the rubber industry may survive without such appointments, but that the whole problem is essentially ecological there can be no shadow of doubt The soil problems as such, though an extremely important part of the whole, by no means exhaust the matter, as Mr Haines is clearly aware, witness his constant stress on competition

The general recognition of the fundamental importance of the ecological approach wherever we have to deal with communities of organisms living together is gradually coming, though it is distressingly slow The ecologist is trained to consider the *whole* set of phenomena presented by such communities, and to discover which are of decisive and which of subordinate importance Only when such knowledge has been acquired in any given case can the problem of rational treatment be successfully attacked There are now young ecologists available—as there were not ten years ago—who have had this training, and it remains for the competent authorities to see that their services are employed in tackling the innumerable problems that await rational solution

Specialists who have had a narrower training and very naturally think that 'there's nothing like leather', very often fail to come to grips with the larger aspects of their problems because they envisage them solely from one side Ecologists can sometimes indicate the best solutions as soon as their survey of the field is completed, but very often experiment and specialised work are necessary after the general survey is completed. This is the proper sphere of the specialist, be he plant physiologist, mycologist, entomologist, pedologist or soil chemist Ecologists have now been successfully engaged in the solution of the most various practical problems in New Zealand, in South Africa, in the United States, and elsewhere, but the fields ripe for their work are innumerable, and the proper management of the modern rubber plantation is clearly one of them A. G T

Economy of Transport Overseas

MERCANTILE vessels can be divided into three main classes—passenger ships, combined passenger and cargo ships and purely cargo ships. Of these it is the first class which receives the greatest attention in the public Press; although the commerce of the world is carried on principally by tramps and freighters, these are seldom in the public eye. Generally speaking, unlike the steam locomotive, which was first used for mineral traffic before its potentialities for passenger traffic had been realised, the steam boat was regarded chiefly as a passenger carrying vessel.

The idea that steam vessels might prove of use for freight carrying, however, was not altogether absent from the minds of the pioneers, and a century and a half ago the oft-forgotten but deserving American inventor John Fitch wrote, "Here is an estimate which I beg leave to make. It takes thirty men to take a boat of thirty tons burthen from New Orleans to the Illinois. Now, I say, if I could be enabled to complete the experiment, I would obligate myself to make a boat of sixty tons burthen which, with engines and all complete, would cost $2,000 As that could work double the time of the men at the oars, it could go half the time, and transport 120 tons in the same time that the other would thirty tons. At the rate now charged this would pay for

itself and clear $10,000 whilst one boat could make one trip—and larger boats could be made to greater advantage"

Fitch was a man of wide vision who did not live to see his dreams come true He has, however, as great a claim as anyone to be regarded as the father of the steam passenger boat and the steam cargo boat. But while conceding this, it is true that both in the United States and in Europe, when steamboats came into use, it was passenger traffic which was regarded as the principal source of revenue

The traffic which, perhaps, led to the construction of the first cargo steamers in Europe was the cattle trade between Ireland and England, and just a century ago the *Glasgow Chronicle* referred to the Clyde-built steamer *Irishman* plying between Drogheda and Liverpool, which was capable of carrying 2,000 head of cattle, and was fitted with stalls for horses and horned cattle and pens for pigs, etc, on deck and in the hold. There was certainly need for improvement in this trade, for Joshua Field in his "Diary" of a visit to Liverpool in 1821 said that during a storm in the Irish Sea in September, "6 or 8 Brigs full of horned cattle and pigs were out in it and I believe all came in during the following day having lost more or less of the cattle killed in the hold and pigs either killed on deck or washed overboard One of them lost 60 pigs overboard and one 70 and the captain They came in mostly on their beam ends, the cattle dead and alive being on one side"

Another traffic which gave rise to steam cargo vessels was the carriage of coal from the Tyne to the Thames In 1844, a Tyneside shipbuilder built an iron screw collier with a deadweight capacity of 340 tons, while eight years later Sir Charles Palmer at Jarrow built the larger *John Bowes*, carrying 650 tons The *John Bowes* could make the voyage from Newcastle to London and back in five days and thus "she accomplished an amount of work it would have taken two average-sized sailing-colliers a month to perform". To the success of the *John Bowes* may, to some extent, be attributed the subsequent rapid development of iron shipbuilding on the north-east coast, a district famous for its construction of tramps and freighters. Similar vessels are to-day built in many yards all over the world and from these yards come not only ships ready to carry any form of general merchandise but also others especially designed for the transport of fruit, meat, grain, coal, ore, oil and other commodities. The greater part of the world's mercantile marine is indeed composed mainly of these cargo ships, of which little is heard.

It has been considered worth while to give this brief sketch of the early history of cargo ships because it was with tramps and freighters that Mr. L St. L Pendred was concerned in the most valuable part of his Thomas Lowe Gray Lecture delivered to the Institution of Mechanical Engineers on November 30 (see NATURE, Dec. 8, p. 875). The title of his lecture, "A Survey of Ships and Engines", left him free to touch upon many aspects of shipbuilding and marine engineering, and in the earlier part he pointed out some of the landmarks in steamship history up to the time when improvements in both ships and engines had enabled cargoes to be carried long distances more economically by steam than by sail

Having got thus far, Mr Pendred devoted himself exclusively to cargo steamers. He had been at some pains to obtain from authoritative sources particulars of ships of the last fifty or sixty years, and his lecture contains two tables, prepared, one by Mr T. W Crozier, for many years manager of the Blyth and Tyne Shipbuilding Co, and another by Mr Summers Hunter, giving particulars of merchant steamers engined between 1867 and 1934 by the North-Eastern Marine Engineering Co. With the aid of these tables, Mr Pendred had prepared a series of curves connecting coal consumption, steam pressures, speed, etc. The progress of tramps, however, he summarised as follows. In 1887 a typical tramp was 285 ft. long, with a displacement of 4,840 tons. The working pressure was 160 lb. per sq. in and the speed 9¾ knots In 1896 the length had risen to 325 ft. and the displacement to 7,075 tons. By 1911 the displacement had risen to 10,000 tons, by 1924 to 11,500 tons and by 1928 to 12,380 tons. Boiler pressures had risen to 200 lb per sq. in. or more, and speeds to 13 knots or more Size has much to do with economy of transport, and Fitch was quite right when he said that "larger boats could be made to greater advantage"

In conclusion, Mr Pendred said, "Further economy in cargo ships must be and will be sought. May it not best be found by extension of the known and approved, by higher propeller speeds, higher pressures, higher temperatures, higher piston speeds, better materials making for lighter structures, better under-water form? These will carry the steam engine forward until, its work well done, it surrenders its place to the internal combustion engine, or to some other prime mover which still lies in the womb of time".

Carriage by sea is the cheapest of all forms of transport, and the reduction in cost during the last century has been remarkable. Even thirty years ago, Sir William White said. "When small vessels were used to transport grain from America the freight was 9*s*. 6*d* per quarter, now it is 9*d*. per quarter from New York in the large cargo-carriers".

Jubilee of the City and Guilds (Engineering) College, London

ON Monday next, February 4, the City and Guilds College, affectionately known to many besides its students as the 'Central', is to celebrate the jubilee of its foundation, the present building having been opened in 1884 It is too near the achievement for us properly to assess the value of the work done in founding and establishing London's and the Empire's premier school of engineering, but it is more than probable that a century hence the historian will regard the movement which led to the establishment of the colleges at Finsbury and South Kensington as outstanding in importance and in the results it produced

From the first, the 'Central' has been characterised by its originality and independence, never were four colleagues so outstanding in this respect as its original professors, Armstrong and Ayrton promoted from Finsbury a year after the establishment of their new building there, Unwin from Coopers Hill and Henrici from University College, London In principle they were in agreement, and each knew they had problems to solve, but each set to work to develop his own department to the best of his ability, and the College developed on these individual lines though also as a whole, and became great perhaps as a consequence

A strong effort was made to make the chemistry course a part of the curriculum of the engineer and to insist on the chemist passing through a comprehensive course in mathematics, physics and the elements of engineering It proved, however, that as a whole the engineers did not want to learn chemistry, chiefly perhaps because the subject never appealed to their mentality, since the tendency of the engineer is to construct and not to think or seek hidden meanings It is of significance in this connexion that scarcely half a dozen of the Centralian engineers have distinguished themselves in chemical engineering, whereas the Centralian chemists, owing in part to their engineering training, have been uniformly successful as pioneers in developing the newer industries. It is still a fact that chemists have to learn engineering and become chemical engineers in order to take part in the enormous developments in chemical industry, and the lack of such trained engineers in Britain as compared with their superabundance in Germany and America has been definitely a handicap.

There is no need to record here how the College has passed from success to success; after the first few years, it was always full with students carefully selected by an entrance examination which grew increasingly exacting. The rapidly developing electrical industry was manned each year by new batches of Centralians imbued with Ayrton's zeal and enthusiasm, and civil and mechanical engineering positions at home and abroad were increasingly filled by Centralians loyal to the Unwin thoroughness Time, alas, brought changes in the professoriate, Mather succeeded Ayrton, Klugh followed Henrici, Dalby came from Finsbury on Unwin's retirement, whilst the Chemical Department was closed when the 'Central' was merged with the Imperial College of Science and Technology, leading to the retirement of Armstrong, who is the only survivor of the four great original founders

So far, the early development of the College has been emphasised and the birth of its traditions, which few will be unwise enough to minimise For the new student tradition must mean much; it is up to him to be worthy of it as Kipling says, "Of one muster all of us, keen in his vocation", whilst, in consequence of the tradition to produce highly trained, reflective, inventive graduates, employers have sought to obtain the 'Central' men as they graduated

Perhaps the first break in the old order came with the inclusion of the 'Central' as a school of the University of London in the Faculty of Engineering in 1899 and the attachment of the University examination and degree in engineering to the diploma of A C.G.I.

To-day the City and Guilds College has its own governing committee, or delegacy, within the organisation of the Imperial College. Its courses are essentially engineering; the number of departments has expanded. There is more specialism, and a number of eminent and devoted professors are giving of their best to training the men so urgently needed for Britain to hold its own in the intense struggle for industrial supremacy. In some ways the requirements are other, more specialised than fifty years ago, in other ways, the need is still the same for men of broad outlook, trained to think and create rather than to memorise and to imitate. The influence of the great teacher, of the man of genius, independence and vigour, is still as great on the student in his most impressionable age, and the College will be wise to select and retain such, be they young or old, whatever may be the cost. Countless biographies of successful men testify to this influence of their teachers on them, prevailing throughout their lives.

The 'Central' has done a great work; it has been well and unselfishly served in the past, it will do so much in the future.

E F. A.

Manufacture of 'Colloidal' Fuel

SINCE 1879, numerous attempts have been made to produce a suitable mechanical mixture of coal and oil that would be capable of retaining the coal particles in suspension for a sufficiently long period and at such temperatures as would be likely to obtain in normal working conditions, where such fuels could be used.

Fairly successful attempts were made in 1918 on the U.S. patrol ship *Gem*, using a blend of 67·8 per cent oil and 31·2 per cent coal dust. More recently, great prominence has been given to this question as a result of experiments made on the Cunarder, S.S. *Scythia*, using a mixture of 60 per cent of oil and 40 per cent fine coal.

Despite these tests, progress in the development of a 'colloidal' fuel has been very slow. This is due to two causes:—first, the difficulty experienced in keeping the mixture in a stable condition where it had to be stored for any lengthy period before use; and secondly, the high cost of pulverising dry coal to a sufficient degree of fineness to make a suitable and stable liquid emulsion.

The former difficulty can be readily appreciated when it is realised that the specific gravities of coal and oil are 1·3 and 0·9 respectively. Various attempts have been made to keep the coal particles in suspension by the addition of fixateurs (such as rosin, paraffin wax, etc.) or by the addition of 'peptising' fluids which tend to increase flotation by splitting up the particles of coal into still smaller particles. While the fixateurs have been more or less successful in increasing the period of suspension, the cost of peptising fluids makes their general use prohibitive.

From the results of a demonstration given by Messrs. Wyndhams Liquid Coal Co., Ltd., at their Cardiff works on January 23, it would seem that their engineer, Mr. Stephen Wyndham, has recently made great progress in overcoming both of the difficulties referred to. In his new plant, he has eliminated the costly process of dry coal pulverisation by mixing the fine coal as received from the colliery with an equal amount of heavy oil and then passing the coal-oil mixture through a series of rolls until a fineness of 99 per cent through a 200 I.M.M. mesh is obtained for the coal particles. This degree of fineness together with the aeration of the mixture which takes place in passing it through the mixer and between the mixer and the successive series of rolls, seems to give a very stable mixture which will retain the coal particles in suspension for at least four months under normal working conditions.

The plant is very simple in construction and no chemical processes are involved. The class of coal used is that known as 'duff' (namely, coal less than $\frac{3}{16}$ in. in diameter) and is fed from an overhead hopper through a worm screw into the rotating mixture where it meets an oil spray, forming a paste of coal and oil. The predetermined quantities of coal and oil forming this paste are automatically regulated in their entry to the mixer, which is fitted with a spiral worm cast on the inside and passing from top to bottom of its 6 ft. length. Although only 18 in. in diameter, it is capable, when working continuously for six days a week, of producing 100 tons of colloidal fuel.

The paste passing from the mixer is pumped to a pair of rolls 8/1000 in. apart, rotating in opposite directions at variable speeds of 3 to 1. It is then pumped to the second set of rolls, which are 4/1000 in. apart, and so on down to the fourth or sixth set, according to the degree of fineness required to produce stability for any particular class of coal.

The cost of one 100 ton per week plant is approximately £1,000. Very little manual labour is required to operate it and the maintenance charges ought to be low, as the principle of wet milling is used throughout the process.

In burning the oil underneath a steam boiler, the fuel is pre-heated to about 250° F., at a pressure of 15–20 lb. per square inch, and the air is maintained at a pressure of 2 lb. In the demonstration test, this gave a clear smokeless flame, without a trace of coking at the burner tip.

It would appear that we are at last within sight of the solution of a problem which has taxed the ingenuity of engineers for at least half a century.

Obituary

SIR E. A. WALLIS BUDGE

IN the course of the year 1934, Egyptology had to record a heavier loss of life amongst its leaders than has occurred in any other single year of its century odd of history. Five of the seven who died were Englishmen; the last was Sir Wallis Budge, for more than thirty years keeper of Egyptian and Assyrian antiquities in the British Museum, and one of the two most widely known Egyptologists that Great Britain has produced. The characteristics that gave him the unique position which he held in the public mind were no ordinary gifts, and are perhaps not to be found combined in our own generation.

Ernest Alfred Wallis Budge was born in 1857 of a Cornish Quaker family, to which no doubt he owed that abiding interest in the study of religions which

was the mainspring of so much of his work In the man himself, assisted perhaps by the not easy circumstances of his early years, lay a 'power of work' which quite transcended mere industry and was his outstanding characteristic and the envy of those who served him As a boy, it attracted the attention of his superiors and eventually won him the backing of W E. Gladstone At Cambridge, it brought him University prizes and an unusually wide and thorough knowledge of Semitic languages with which to start his official career in the British Museum

The bare record of Budge's exceptionally early promotion to the full responsibility of keepership, followed by nearly two columns of "Publications", are still to be read in the current "Who's Who" But no mention is made there of the period during his assistantship, when, after the retirement of Renouf, the responsibility for the Department was his, without the privileges of the appropriate office In two fat volumes, "By Nile and Tigris" (published 1920), parts at least of the adventurous life at home and abroad, which lay behind those dates and titles, are to be found. It is a story of vital and impressive contacts with the great pioneers of Egyptian and Assyrian studies, and of lasting gratitude to early masters, of missions on the Trustees' behalf to Egypt and Mesopotamia, covering a period of nearly thirty years; of the famous action for slander—*Rassam v Budge*, of which the extensive account from the issue of NATURE for August 10, 1893, emphasises the national interest at stake and more than vindicates Budge's part in the case This unofficial account of a scholar-civil servant's official career was as near as its author could permit himself to come to an autobiography, but we may guess that it tells only half the tale, and no one who reads it can escape the regret that we shall never know the rest

Neither the long tenure of his office nor his massive learning could by themselves have made Budge the public figure that he was; though both contributed to his fame It was the vigour and quality of his personality that endeared him and 'made his name to live' on the lips of as many thousands as there were individuals who came to blows with him professionally. But no man of his virility could fail to make enemies; nor could one of his positiveness easily escape criticism, some of it deserved. His worst enemies would not deny that he was possessed of prodigious learning; but inaccuracy in its setting forth rendered him liable to endless attack That charge was not always a just one. His most important scientific work, which naturally was that most criticised by his colleagues, was the edition of texts, generally of considerable length, in many languages—Assyrian, Egyptian (Hieroglyphic and Hieratic), Coptic, Ethiopic, Syriac. It was a principle with him that in editing ancient authors his business was simply to present their text in a printed form which would be accessible to modern scholars. The correction of mistakes in the text, if indeed they were mistakes, was a secondary and later task with which he was not concerned. As a result, he sometimes received the censure which should have been addressed to the original scribe of the manuscript in question There was something to be said on both sides of the argument, but however strong the attack, Budge's claim to be accounted among the great Oriental scholars of the last fifty years will grow rather than fail as personal considerations automatically die, leaving the impressive series of his editions of primary texts to speak for themselves

Then again, the extraordinary number and size of the books which Budge turned out, the majority necessarily of a popular or semi-popular nature—while a matter of pride to himself—was often counted against his reputation But in truth, it was a part of his greatness that he knew how to do what no other Egyptologist in Great Britain could do by writing, namely, to bring his subject within the reach of the ordinary reading public Nor were his books a mere popularisation of that side of Egyptian studies which might be supposed to have a natural attraction for the man in the street Any teacher of the subject, and still more any museum official familiar with the endless stream of inquiry on matters Egyptian which pours through the British Museum, is well aware that almost all stock questions relating to the history, customs or antiquities of Ancient Egypt can be most expeditiously answered by referring the inquirer to one or another of Budge's handbooks. The secret of his success lay, of course, in his Museum experience Budge was above all things a devoted public servant, and after he had retired from the Museum and until the last, he remained as jealous for the authority and privileges of the Trustees, the representatives of the public, as he had been loyal to their interests during his service

The tradition of scholarly research and authoritative learning in the subjects with which they dealt stood high among the officials of the British Museum when Budge entered it, but he was one of the first to bring that wealth of knowledge within the reach of the general public, even though, for various reasons, some of the methods he used would not now be considered good museum technique, or even effective for the purpose he sought. But it was of paramount importance that he should have been so fully conscious that the antiquities under his charge were the property of the nation, and that it was therefore his duty, first to take proper care of these antiquities, and secondly to make them as much available to the nation as was possible. He had his own clear ideas as to the manner in which both purposes should be achieved; and both brought him into conflict with authority. But he knew that in principle he was right, and he was proud to think that his knighthood was the reward not of his contribution to scholarship, nor of his success as a populariser of a branch of learning, but to the faithful performance of his stewardship. It was from his determination to serve the public that he learned what they wanted—or at least, what they thought they wanted—and gave it to them so successfully in his books and in the galleries under his charge. S. R. K. GLANVILLE.

Sir Maurice Craig

PSYCHIATRY has suffered a grievous loss by the death on January 6 of Sir Maurice Craig, consulting physician in psychological medicine to Guy's Hospital, and consulting neurologist to the Ministry of Pensions Born in 1866, he received his education at Bedford Grammar School and Caius College, Cambridge. He was early interested in mental disorders, and was one of the many distinguished men who have gained the Gaskell Gold Medal of the Royal Medico Psychological Association.

For more than fifteen years, Craig was a resident physician at Bethlem Royal Hospital, years in which he gained a very wide experience in psychiatry, and in the teaching of the subject to students From 1907 Craig confined himself to consulting work, and built up a very extensive practice He delivered the Bradshaw Lecture at the Royal College of Physicians on "Mental Symptoms in Physical Disease" in 1922, and the Maudsley Lecture on "Some Aspects of Education and Training in Relation to Mental Disorder" in the same year In addition to numerous articles in medical journals, Craig published a book on "Nerve Exhaustion" which was much discussed on its appearance In 1905 the first edition of his well-known textbook on psychological medicine appeared, after exhausting three editions, the book was revised and rewritten in co-operation with Dr. Thomas Beaton and republished as the fourth edition in 1926

During the War, Craig was a valued adviser on the care and treatment of nervous and mental disorders among officers and soldiers, and afterwards became consulting neurologist to the Ministry of Pensions, and a member of the War Office Committee on shell shock. He received the C B E in 1919, and the honour of knighthood in 1921

Sir Maurice Craig developed a profound interest in the early evidences of mental disease, and throughout his teaching life insisted on the importance of early symptoms. During the years of his consulting work, he became increasingly concerned in what are known as the psychoneuroses and neuroses He was an enthusiastic and hard-working chairman of the medical committee of the Cassel Hospital at Penshurst, and chairman of the National Council for Mental Hygiene up to the time of his death.

Sir Maurice Craig enjoyed a very wide esteem and popularity among his professional brethren. He was made a governor of the Royal Hospitals of Bethlem and Bridewell; he became the president of the Section of Psychiatry, Royal Society of Medicine, and president of the Section for Mental Diseases at the centenary meeting of the British Medical Association in 1932 He was a vice-president of the International Committee for Mental Hygiene. His many appointments reflect his scientific interests, and his universal popularity.

It is impossible to write of Sir Maurice Craig without remembering his charm of manner, his delightful presence and popularity. He was ever ready to help and encourage a younger colleague, and was tireless in his devotion to his patients. Yet he could be quite fearless and outspoken in debate or criticism. His contribution to psychiatry may be summarised by his constant insistence on the importance of early symptoms in every form of mental disease, and the urgent need of early treatment; by his leadership in making psychiatry a part of general medicine, and freeing it as far as possible from legal restrictions; by the stimulus he has given to improving the education of medical students, practitioners and the general public in matters of mental health and hygiene Lastly, Craig has focused a keen scientific inquiry on the place taken by fatigue in the etiology of mental disease His death will be deplored by a very wide circle of scientific men

The Rev S A. McDowall

THE death on January 13 of the Rev S A. McDowall, chaplain and senior science master at Winchester College, will be felt as a deep personal loss by many Wykehamists and a wide circle of friends.

Stewart McDowall went up to Trinity College, Cambridge, from St Paul's School and obtained first classes in both parts of the Natural Sciences Tripos. He became a demonstrator in the Biological Laboratory and assistant superintendent of the Museum of Zoology at Cambridge. In 1905 he joined the staff of the Christian College at Madras as temporary professor of zoology, and a year later was appointed an assistant master at Winchester College In 1908 he was ordained, and in 1915 became one of the College chaplains In the same year he published the first of a number of works on science, philosophy and religion "Evolution and the Spiritual Life" was the first expression of his beliefs that evolution was the method by which God had chosen progressively to create free beings, and that science had great gifts to bring to the service of the Christian world

McDowall was a select preacher at Oxford 1916, at Cambridge 1920, and Hulsean lecturer 1923–24. "Evolution and the Doctrine of the Trinity" appeared in 1919, and the Hulsean Lectures were published as "Evolution, Knowledge and Revelation" Meanwhile, he had been appointed senior science master at Winchester College in 1918, and since that time had much to do with the development of the science teaching both of science specialists and of a general science course which is taken by the whole of the upper part of the school.

McDowall held vigorously the view that every citizen should have sufficient training to appreciate the scientific problems which only the highly specialised technician can be expected to solve, and that all should have some acquaintance with the history of man's growing control over his environment, particularly as it has been attained by scientific methods. During the last year of a boy's school life, he aimed at introducing to him the facts and theories of modern biology in their bearing on the life of a civilised community. His views on this subject were incorporated in his last book, "Biology and Mankind", published in 1931.

For many years McDowall was curator of the College museum and president of the Natural History Society, of which the biennial reports show the

wide range of interests which he inspired in his young friends. To his psychological knowledge and insight, and to his sympathy with differing minds, Dr William Brown has borne eloquent witness in *The Times*. He was a man of great personal charm and a brilliant conversationalist His intellectual and æsthetic interests were very wide and led him to seek new experiences and to encourage others to share them Successive generations of Wykehamists testify to the way in which he stimulated the development of their minds by his own enthusiasm for life

Mr Kenneth F Armstrong

The death of Kenneth Armstrong on January 3, at twenty-five years of age, while on a visit to the Austrian Tyrol with another young and promising Oxford graduate, John Howard, who was an old schoolfellow, is a grievous tragedy. While ski-ing, they encountered an avalanche which seems to have swept Howard to his death, and it appears that Armstrong, in his endeavour to recover his companion, fell into a ravine, being killed as the result of crashing on a rock

Armstrong was the son of Dr E. F. Armstrong and the grandson of Prof H E Armstrong His death is a personal shock to everyone who knew him, and it is regrettable that chemistry should be deprived of the contribution to its progress so clearly destined to come from his labours. There can be no doubt that, had he lived, he would have done full credit to his scientific ancestry

Armstrong received his early education at Oundle School, whence he went to Magdalen College, Oxford, in 1927, having been awarded a demyship there He gained a first class in the Honour School of Chemistry at Oxford in 1931 After graduating, he was awarded a Julia Henry scholarship and proceeded to Harvard University and commenced work on chlorophyll problems with Prof J B Conant In the two years spent there, he made a valuable advance in this difficult field, and part of the work has been published in the *Journal of the American Chemical Society* Armstrong's extensive knowledge of this subject enabled him to contribute a lucid article on present-day knowledge of chlorophyll to *Chemistry and Industry*.

Soon after his return to Oxford in 1933, Armstrong was elected to a Harmsworth senior scholarship at Merton College and was quickly at work on several problems of his own choice Among these were · the nature of the colouring matter of the red moth , the identity of the glucoside in the Japanese laurel (*Aucubine*) ; and the configuration of the cyclic polyalcohols, particularly quebrachol. Recently, in collaboration with Prof R Robinson, some work on the oxidation effects of selenium dioxide was published. Armstrong recently collaborated with his father in producing a new edition of the well-known books on the simple carbohydrates and the glycosides.

His friends will ever remember with respect and admiration Armstrong's unfailing kindliness on all occasions. His lamented death deprives the Oxford school of organic chemistry of one of the most notable of the younger generation of research students.

Dr. Eleanor Hull

We regret to record the death of Miss Eleanor Henrietta Hull, folklorist and Erse scholar, which took place at the age of seventy-five years, on January 14, at Wimbledon

Miss Hull was the daughter of Prof Edward Hull, and was educated at Alexandra College and the Royal College of Science, Dublin She studied Celtic and allied subjects under Pedersen, Kuno Meyer and R. Flower An enthusiast for the study of Irish history and letters, she added sound scholarship to the movement for the revival of Erse and the rekindling of pride in Irish tradition Apart from her own literary work, this took practical form in the foundation in 1899, with the assistance of Prof York Powell, of the Irish Texts Society As honorary secretary of the Society she enlisted the services of the foremost Erse scholars of the day, and was largely responsible for the publication of a number of valuable and important early Irish manuscripts. Miss Hull was at one time secretary of the Royal Asiatic Society She had served as president of the Irish Literary Society of London and was a member of the Council of the Folklore Society

Among her contributions to Irish studies her work on the Cuchulain Saga (1898) will always hold first place , but as a folklorist her "Folklore of the British Isles" (1928), in bringing some sort of system and order to the treatment of a mass of somewhat chaotic material, runs it close Among other works worthy of note were her "Pagan Ireland and Early Christian Ireland" (1904), "A Text-Book of Irish Literature" (1906–7), "Cuchulain, the Hound of Ulster" (1909), and a "History of Ireland and Her People" (1926, 1931) in two volumes

We regret to announce the death of Arthur Lionel Pedder, on December 15, at the age of sixty-six years. He was mathematical tutor at Magdalen College, Oxford, from 1891 until 1925. He went to the College as a demy in 1886, and was elected fellow in 1894 Pedder was a very good teacher and was remembered with gratitude and affection by his pupils He was one of the old-fashioned people who valued the educational training given by the curriculum and examinations of the old mathematical school as one of the best preparations for after-life , and was quite out of sympathy with the new system which, in his opinion, was of little or no use, except for those who intended to be professional mathematicians.

We regret to announce the following deaths :

Mr. F. J Blight, fellow of the Royal Society of Edinburgh and formerly chairman and managing director of Messrs Charles Griffin and Co., Ltd., publishers of many scientific and technical works, on January 27, aged seventy-six years.

Dr. Michael Grabham, author of numerous books and papers on the natural history of Madeira, where he had lived for some seventy years, on January 28, aged ninety-five years.

News and Views

Prof. Arthur H Compton

THE Guthrie lecture of the Physical Society is being delivered this year at the Imperial College of Science and Technology, South Kensington, on February 1, by Prof Arthur H Compton, of the University of Chicago Prof Compton, who is at present Eastman visiting professor at the University of Oxford, is perhaps best known for his discoveries of the laws of interaction between radiation and free electrons, and for the associated effect, called after him, which results in a modification in the quality of a beam of monochromatic radiation such as X-rays on passing through matter It was for these discoveries that he was awarded the Nobel Prize for physics in 1927 He is also one of the leading authorities on X-rays and the author of one of the finest books on this subject In recent years, Prof. Compton has turned his attention mainly to the investigation of the cosmic rays, those mysterious and exceedingly penetrating radiations which come into the earth's atmosphere from outside. In this connexion he has organised twelve expeditions, with the collaboration of about a hundred physicists, which have made a cosmic ray survey of the globe He also initiated, and was scientific director of, the balloon flight of Settle and Fordney in November 1933 for investigating conditions in the upper atmosphere, which achieved what still remains the official world's record altitude of 11 8 miles

Prof. Arthur Lapworth, F.R.S.

PROF ARTHUR LAPWORTH, who is Sir Samuel Hall professor of chemistry at the University of Manchester and director of the chemical laboratories, is retiring in September next. Prof. Lapworth joined the staff of the University of Manchester in 1909 as senior lecturer in chemistry, on vacating his lectureship at Goldsmiths' College, London He was appointed professor of organic chemistry in 1913, and Sir Samuel Hall professor and director of the laboratories in 1922 He was appointed pro-vice-chancellor in February 1933, and it is a disappointment to the University that his health has not allowed him to exercise the functions of this office during the last few months During his time at Manchester, Prof Lapworth has published work in a number of branches of pure organic and physical organic chemistry; he will be remembered for his investigation of the terpenes, his work on certain natural products carried out in association with the Oil and Fats Committee of the Food Investigation Board, and especially for his studies on reaction mechanism and molecular reactivity, which led to the initiation of the now famous 'electronic' theory of organic reactions. He has been awarded honorary degrees by the Universities of Birmingham and St. Andrews, and received the Davy Medal of the Royal Society in 1931. His retirement will be a source of deep regret to his many colleagues and students.

Centenary of Friedrich Winnecke, 1835–97

ON February 5 occurs the centenary of the birth of the distinguished German astronomer, Friedrich August Theodor Winnecke, who at the early age of twenty-eight years was elected an associate of the Royal Astronomical Society, and was for a time the vice-director of Pulkova Observatory The son of a pastor, Winnecke was born in a village in Hanover, and after leaving school studied at Göttingen and Berlin, coming under the influence of both Gauss and Encke At the age of twenty-one years he became an assistant at Bonn to Argelander, who was then engaged on his great star maps A visit by Wilhelm Struve to Bonn led to Winnecke in 1858 becoming a member of the staff at Pulkova, where he worked under both Wilhelm and Otto Struve, until in 1865 he was overtaken by severe mental illness During those years he had observed the comets of 1856 and 1862, watched in Spain the total solar eclipse of 1860, made notable observations on Mars and compiled the first Pulkova General Catalogue of Stars When he regained his health, he settled at Carlsruhe, and after the conclusion of the Franco German war was appointed to the chair of astronomy at Strasbourg and charged with the task of erecting an observatory. He spent some ten years there, when to the great loss of astronomical science he was attacked by melancholia and from that time until his death at Bonn on December 2, 1897, the cloud which settled on his mind never lifted He had been a frequent contributor to German, English and Russian astronomical publications, and was widely known as a great teacher of practical astronomy.

Anniversary of Prof. F. Haber's Death

TUESDAY, January 29, was the anniversary of the death in Switzerland of Prof. Fritz Haber, and a memorial ceremony at which certain of his distinguished German scientific friends were to speak had been arranged by the Kaiser Wilhelm-Gesellschaft in co-operation with the German Chemical Society and the German Physical Society It was to have been held in the Harnackhaus, than which no more appropriate surroundings could have been found, and a pleasant impression had been made among Haber's friends that these three great German scientific societies were prepared to honour so soon the memory of one of their greatest members, though he had been among those men of science who had given up their positions through the political changes in Germany The Prussian Minister of Education, however, in a letter dated January 17, addressed to the rectors and teaching staff of the universities, has expressed surprise and disapproval of this proposed memorial According to this circular, Prof. Haber was dismissed on October 1, 1933, on account of a proposal which could only be regarded as showing his opposition to the measures taken by the National-Socialistic State. The ceremony seemed to the

Minister to constitute a challenge to the State, particularly since such memorials were to be held in honour only of the 'very greatest' Germans. The circular consequently concludes by forbidding all officials and all other members of staffs or institutions under the Ministry from attending the ceremony. It is difficult for scientific workers outside Germany to understand why a Minister of State should prohibit the commemoration of the great services rendered to that country and to the world by Haber, or what must be the feelings of the members of the societies concerned with the organisation of the proposed ceremony. Chemists and physicists throughout the scientific world acknowledge Haber's work as epoch-making, and Germany should be proud to cherish his memory. Truly in his case the Prussian Minister of Education now makes it clear that, officially, "A prophet is not without honour, save in his own country and in his own house".

Intensive Farming and Security of Tenure

THE Metropolitan Water Board is promoting a Bill in the present session of Parliament to acquire the Holly Lodge Farm, Walton-on-Thames, owned by Mr. A. F. Secrett, for the purpose of making a storage reservoir. Mr. Secrett is well known in the horticultural world as one of the leading growers of vegetable produce for market. He has been particularly prominent in developing the growing of early vegetables, winter salading, etc., hitherto almost wholly supplied by French and other continental growers, and by his willingness to impart his knowledge of the management of these special crops, he has contributed more than anyone else to provide the home market with these products. The farm consists of 187 acres, of which 165 are now in intensive cultivation. One acre is under glass, three acres are under frames for early lettuce, etc. The seakale beds, traversed by an underground hot water system, extend to about $\frac{1}{8}$ acre. The whole farm has been redrained so as to lower the winter water table 4–6 ft. below the surface. The irrigation system, with its own well and pumps, covers 125 acres, requiring $2\frac{1}{2}$ miles of pipes. No other agricultural enterprise in Great Britain of this magnitude can show an equal intensity of cultivation; for example, a capitalisation of £81 per acre (exclusive of land), an output of £142 per acre, a wage bill of £62 per acre. No less than 10,000 tons of dung have been brought on to the farm for this year. It is noteworthy that Mr. Secrett, as a pioneer in his special business, has always been willing to instruct others; at the present time he has taken on fourteen young men to gain experience of his methods. They pay no premium and receive the ordinary wages; once each week Mr. Secrett lectures to them and explains his procedure.

THE destruction of this business could not adequately be met by even the high compensation which Mr. Secrett might obtain. The site is a special one selected by Mr. Secrett after long search; it would be extremely difficult, indeed it might be impossible, to obtain an equivalent piece of land, which even then would require some years to equip and bring to a similar pitch of fertility. Doubtless very careful consideration has been given to the selection of this site for a reservoir, but it is difficult to suppose that no alternative exists. Mr. Secrett's farm stands pre-eminent as an example of the productive enterprise which the Government's agricultural policy is trying to foster, and of exceptional employment upon the land; under nothing short of absolute necessity should it be allowed to be submerged. Had the farm been a factory employing a hundred workmen and engaged in some new process, the Metropolitan Water Board would have thought twice about disturbing it. Yet it is a simple matter to rebuild a factory compared with the difficulty of finding a site and the time required to bring it into condition in order to replace the outfit represented by Holly Lodge Farm.

Aboriginal Reserves in Australia

THE attention of the public in Australia has again been directed to the urgent problem of the aborigines and their reserves. On this occasion the method employed to secure its consideration has been unique. According to a dispatch from the Melbourne correspondent of *The Times*, which appeared in the issue of January 24, a deputation of ten full-blooded aborigines waited upon Mr. Paterson, the Minister of the Interior, to urge, among other matters, the establishment of a Federal Department of Native Affairs, under a sympathetic administrator such as Sir Hubert Murray, the present Lieut.-Governor of Papua, and the institution of an advisory council, which would include social, anthropological, medical and educational experts. The spokesman of the deputation directed attention to the serious economic situation now arising among the aborigines. He pointed out that they are being driven into barren wastes in which it is impossible for them to live. He also pledged the aborigines as Commonwealth citizens, believing that the British Empire stands for justice, order and freedom, to maintain their heritage handed down to them by the Creator, but suggesting in what followed that present conditions were not favourable to that end. This is a somewhat surprising, but none the less significant, indication of recent developments in the movement for the improvement of the lot of the aborigines. It is probable, and, in fact, certain that the Australian public generally is not very fully informed of conditions of life among the aborigines. The mere size of the reserves has tended to obscure the relation to the area requisite for subsistence to the mode of subsistence. It is not realised that a considerable range of land is needed for the support of even small groups of food gatherers such as those found among the Australian aborigines. The formation of a Department of Aboriginal Affairs, of which the consideration is promised by Mr. Paterson at the next conference of Premiers, would ensure a more carefully reasoned control of aboriginal territory in relation to their needs and mode of life.

Ancient Greece and Modern Civilisation

IN his Friday evening discourse delivered at the Royal Institution on January 25, Sir Richard Livingstone discussed the relation of modern civilisation to ancient Greece. Starting in a world where men believed that Zeus made thunder and that the sun and moon were gods, the Greeks originated science Their actual scientific and philosophic achievement was remarkable (witness Aristarchus's discovery of the heliocentric system, the anticipation of modern thought in Anaximander's notion that men originate from animals of a different species, and Democritus's atomic thery) But even more remarkable is the grasp on the ideal of science shown in such sayings as "Thought is the supreme ex cellence of men and wisdom consists in saying what is true and acting according to Nature, listening to her" (Heraclitus), and "It is a sin that Reason should be the subject or servant of anyone, its place is to be ruler of all" (Plato) Further, they grasped the idea of a civilisation based on the development of the useful arts This appears in the myth of Prometheus as expounded by Aeschylus, in the "Antigone" and in many other passages in Greek literature In this sense the Greeks were the creators of the characteristic spirit of modern civilisation They grasped the ideal of science as completely as any of their successors We have carried scientific discovery and technology to heights of which they never dreamed But they formed a clearer and perhaps higher conception than we of the life which men should lead against the background of material civilisation They can correct our civilisation not only by the example of an existence, of which Goethe said that of all men the Greeks had dreamed the dream of life best, but also by reminding us that life is essentially a human problem and that ethics and political science are as fascinating as, and even more important than, physical science

Radio Research

A DISCOVERY of great theoretical and practical significance in radio transmission was made last year Listeners to foreign stations have, for some time past, noted that their reception was sometimes marred by a faint background of sound apparently made by a high-power long-wave station At first, lack of selectivity in the receiver and possibly cross modulation were suspected According to Prof. E. V. Appleton, in a paper in the *Electrician* of January 25, the interference is due to a cross modulation effect in one of the ionised layers in the atmosphere The effect was first noticed in connexion with the powerful Luxembourg station, so it is generally called the Luxembourg effect Recently amateurs belonging to the Radio Research League have shown that the phenomenon is also produced by the high-power stations at Droitwich and Athlone. Apparently a long-wave station of this type can impress the waves it produces on the ionised layer in its vicinity. If waves of another wave length are reflected there, they acquire the modulation in question during the process of reflection. The present tendency of increasing the power of long-wave senders makes this phenomenon of practical importance. It brings about a type of interference over which the radio engineer has no control Prof Appleton comments also on the propagation of ultra-short waves (less than 8 metres) They are of importance because of their possible use in television Apparently there is no acceptable evidence that 'round the world' communication will ever be possible with such short wave-lengths The lowest possible wave-length appears to be determined by the finite value of the electrification in the upper atmosphere

International Comparison of Radio Frequency Standards

THE technique of modern radio communication demands a very high degree of precision in the control and measurement of frequency Considerable attention is therefore devoted by the more important national administrations to the development and maintenance of accurate frequency standards In Great Britain one of the standards installed at the National Physical Laboratory provides a frequency of 1,000 cycles per second, the stability of which is better than one part in ten million In order that this standard may be compared with those of other countries, the derived alternating current is used to modulate the carrier wave of a radio transmitting station At the distant receiving station the modulation is extracted from the arriving signal and its frequency is compared with that of the local standard In this manner frequency comparison measurements may be carried out simultaneously in different countries. Under the auspices of the Union Radio Scientifique Internationale, and with the co-operation of the British Broadcasting Corporation, such an international frequency comparison will be carried out during the night of March 12–13 next On this occasion, the output from the frequency standard at the N.P L will be employed to modulate waves from the Droitwich, Scottish National and Scottish Regional stations of the B B C, simultaneously with the frequency of 1,000 cycles per second, for a period of about an hour and a half The object of using several stations is to enable observations to be made on two or three carrier frequencies simultaneously, so that the effect of fading phenomena on frequency stability may be studied On the same night a special emission of a constant frequency of five million cycles per second will be made from the U S Bureau of Standards, Washington, of sufficient intensity for satisfactory reception in Europe Persons and organisations desirous of making use of any of these emissions may obtain further details from Dr E. H. Rayner, president of Commission I of the U.R.S.I, at the National Physical Laboratory, Teddington, Middlesex.

Protection of Wild Animals in India

IT is a welcome sign for the welfare of the wild fauna of India that the editor of the *Indian Forester* (November 1934) should support whole-heartedly F. W. Champion's appeal in the *Journal of the Bombay Natural History Society* of April. Forestry

officers possess great power of determining the fate of the inhabitants of the areas under their control, and while complaints have been made here and there of excessive shooting on the part of the officers themselves, in most areas their influence tells for the preservation of forest animals. Fluctuations in numbers must be expected, and in the United Provinces, while tigers appear to have increased in numbers, marked decreases seem to have taken place amongst nilgai, kakar, wild dog and black buck. The decreases are attributed to serious floods and rinderpest epidemics, and these may be temporary; but the decrease of wild dogs is due to the large reward paid for their destruction. It is unfortunate that the author speaks with two voices about the relative abundance of game at the present day.

Gradual Decrease of Game in Reserved Forests

IN the earlier part of his article, Mr. Champion gives as his definite conclusion that "taken as a whole the head of game shot recently has generally shown no marked decrease, except in the mountain reserved forests, where control is not so easy", and again "the impression of senior forest officers is that . . . the game in the United Provinces Reserved Forests as a whole has not markedly decreased during the last 25 years, except in the high hill forests". But before concluding his article he reconsiders the matter, and the result is by no means so encouraging: "I am not so certain as I was that the head of game inside the United Provinces Reserved Forests is not decreasing. . . . Although still a good place for animals in 1931, I would estimate that there had been at least a 25 per cent decrease in nearly all species during the previous decade." The decrease he puts down to the ease with which shooting can now be prosecuted owing to motor cars, and the destruction of game in areas outside the forests, which results in a smaller influx into the forests, and along with this the greater damage done to animals straying from the forests. Although the position in the reserved forests is not so serious as in outlying areas, it appears to have definitely deteriorated, and in view of this it is unfortunate that the earlier misleading statement was not deleted or modified before the article appeared in print.

Electrical Control of Road Traffic by Vehicle Actuation

THE control of road traffic by means of vehicle-actuated signals is making rapid progress. In a paper read to the Institution of Electrical Engineers on January 24 by Mr. T. P. Preist, the relative merits of the control of road traffic by traffic officers and by time-controlled signals are discussed. The great advantage of using traffic officers is that they are able to take advantage of any useful break in a heavy stream of traffic and so reduce the time interference to a minimum. A drawback is that they are not conspicuous; this could be reduced by mounting them on a raised platform or crow's nest, but even this is not always effective, and a driver in the rear has to deduce the signals from the movements of the vehicles ahead. They also favour unduly horse-drawn vehicles and stragglers. With automatic lamps the signals are highly visible and control the traffic of vehicles before officers could see them from the cross-roads. On the other hand, the system is quite inflexible and may lead to much waste of time. Although railway practice has provided much valuable information to designers of road traffic control, there is a great difference between the fixed path of the railway train and the haphazard paths of the road vehicle. Mr. Preist pointed out a useful analogy between the road traffic problem and the problems that arise in telephony. Both arts have to select and control particular paths from the total available and ensure the orderly passage of the chance traffic arriving on those paths. In telephony the 'traffic' is concerned more with areas than with intersections, and future progress of road traffic control will probably lie in this direction.

Recent Acquisitions at the Natural History Museum

AMONG the recent acquisitions at the British Museum (Natural History) is a collection of 910 Coleoptera comprising 197 named species of Carabidæ (Trechinæ) and 257 species of Silphidæ (Bathysciinæ and Catopinæ) received from Dr. R. Jeannel, director of the Muséum d'Histoire Naturelle of Paris. The main interest of these two groups of beetles is that they include the beetles that inhabit the extensive limestone caverns both of Europe and America. In the course of the ages that have elapsed since their ancestors left the free air and sunlight, various modifications for a cavernicolous habit have been evolved; thus, they have completely lost their eyes, their colour is an almost uniform reddish yellow, their legs have tended to lengthen while their wings have tended to disappear, and in some groups have been entirely lost, and their long isolation as separate colonies has brought about the evolution of distinct species in each different system of caverns. The Department of Mineralogy has received by exchange a portion (4,036 gm.) of a new meteoric stone from Lake Labyrinth in South Australia. A large series of specimens from the Libyan Desert has been collected by Dr. L. J. Spencer, keeper of minerals, while on the expedition of the Survey of Egypt to the Sand Sea in December. The object of the expedition was to investigate the origin of the lumps of pure silica-glass found on the surface in the stony or gravel 'streets' between the high (300 ft.) north-south dunes near the border of Italian Cyrenaica. Wind-worn pieces of clear glass were found in abundance over an area of 200 km. × 40 km., the largest lump weighing 16 lb. Many of the pieces had been broken by primitive man and were associated with hundreds of thousands of flakes of glass and quartzite. Querns and grinding stones were frequently found, and at one spot sixty fine palæolithic axes of quartzite, 8–10 in. long, were found. The region must at one time have supported a large population, but now not a living animal or plant is to be seen. Unfortunately, the glass could not be traced to any source. Another kind of silica-glass was found in the form of lightning-tubes or fulgurites, made by

the fusion of the sand when the dunes were struck by lightning These are paper-thin tubes ¼ in to one inch in diameter and penetrating downwards to the depth of eight feet or more

THE Department of Botany has been presented with the remainder of W Barton's herbarium excepting the genus *Rosa* The present consignment is of about 12,000 sheets with carefully mounted and well-arranged plants, the whole in an excellent condition The herbarium includes that of H J Riddelsdell and Mrs Foord Kelsey It is chiefly British, but includes some Alpine collections. The 20,000 sheets make an extremely valuable addition to the collections Mr N Douglas Simpson has presented about 500 flowering plants from the Anglo-Egyptian Sudan These form a most useful gift as they supplement the collection made by J E Dandy, assistant keeper in the Department, on his recent expedition A collection of 750 flowering plants by H H. Slater from Iceland, Nova Zembla, Kolquev, has been purchased, it fills some gaps in the Department's extensive series of northern plants Seven note-books which formerly belonged to Edward Forster (1765–1849) have been purchased from the Saffron Walden Museum They contain a good deal of information about the plants he collected, and can now be again associated with his herbarium which has been in the Department of Botany since 1849. Robert Brown purchased it at the sale of Forster's books and herbarium, and it formed the nucleus of the British Herbarium

Cambridge University Botanic Garden

CONSIDERABLE publicity has been given in the Press to the will of the late Mr R R Cory, who was, in his lifetime, a generous benefactor of the Botanic Garden in Cambridge He bequeathed the residue of his estate to the University for the benefit of the Garden, with the provision that the income from £30,000 of the residue should be used for certain specific purposes This has led to the impression that the Garden would now be provided with an adequate income Prof A C Seward, professor of botany in the University of Cambridge, informs us, however, that "because of annuities created by Mr Cory's will, the University should not expect any income for the Garden from his estate for many years to come. This means that the help hitherto given by the 'Friends of the Botanic Garden', by the promoters of the Somerset Employment Fund and by others interested in the Garden will be as urgently needed and as gratefully received as in the past."

Fireball of January 3, 1935

MR. A. KING, 53 Victoria Road, Ashby, Scunthorpe, Lincs, sends us the following particulars of this object: At 9h. 24½m. in the evening of January 3 a fireball, which was nearly as bright as the full moon, shot across south-west England. There were about sixty observations, ranging in place from Peterborough to 10 miles south of Falmouth. From the best of these the following path was deduced: Began, 55 miles high over English Channel, 23 miles south of Christchurch, mean deviation, 3·0 miles Ended, 20 miles high over 4m. south east of Wotton-under-Edge, Glos, mean deviation, 1·8 miles. Length of visible track, 92 miles, speed, 13 miles per sec. Radiant, 76°–15°, altitude, 22 6° The fireball exhibited remarkable colour changes during its flight, and drew out a red tail A double detonation was heard at Dursley, at Crewkerne the object was seen to split into two halves towards the end of the path, which would seem to account, on the assumption that each piece set up its own shock-wave, for the Dursley observation The velocity, allowing for air resistance, was of the parabolic order Assuming parabolic speed, the application of the correction for zenith attraction brought the radiant-position to 77°–20° and yielded the orbit ι, 20 5°; π, 139 2°; Ω, 102·6°; q, 0 8865 The theoretical parabolic speed was 14¼ miles per second

Bibliography in Entomology

THE annual meeting of the Royal Entomological Society of London was held on January 16 In his presidential address, Dr S A Neave took as his subject the development of bibliographical work relating to entomology After dealing briefly with the growth of bibliographical compilations on the subject, Dr Neave described the organisation responsible for the production of the monthly issues of the *Review of Applied Entomology* His own very close connexion with the founding and growth of this periodical enabled him to give to his audience an intimate explanation of the manner in which the literature is surveyed and abstracted · the details of editorial duties and the work of preparing the elaborate indexes which are so prominent a feature in each completed volume This well-known publication enjoys a world-wide circulation, and aims at keeping workers posted, by means of summaries, in the vast literature pertaining to the agricultural, medical and veterinary aspects of entomology

Vocational Guidance in the United States

THE vocational guidance scheme which has been in operation in Great Britain for twenty-one years was recently reviewed at the request of the Minister of Labour by a committee of the juvenile employment councils. On the other side of the Atlantic also the 'coming of age' of vocational guidance as a function of the State has been recognised, and the very wide implications of the 'new deal' in this regard are discussed by the associate professor of education and sociology in the University of Pittsburgh in an article in *School Life* of September. It is pointed out that, in the past, vocational guidance has to a large extent been stultified by the gross inequalities in occupational rewards—inequalities which it is one of the purposes of the 'new deal' to reduce. Further, it has been a matter of national pride that everyone has the right to aspire as high as he will, regardless not only of social position and antecedents but also of apparent qualifications of intellect and character, and however obvious it may be to a vocational adviser

that his aspirations are incommensurate with his abilities Now for the first time the view is tenable that society will not tolerate the waste involved in maintaining this conception, already largely illusory, of the individual's right to freedom of choice of occupation A guidance far more positive and compelling than hitherto will obviously enhance the importance of the agencies responsible for it and, moreover, all teachers, supervisors and curriculum-makers will be increasingly preoccupied with their function of exploring and testing their pupils' capabilities

Burden Mental Research Trust

AT a meeting held recently in London, the committee of administration had before it reports of the first year's working of the Burden Mental Research Trust, which Mrs R G Burden endowed a short time ago with £10,000 The investigations contemplated by the Committee are being carried out by Dr J A Fraser Roberts, assisted by Dr R M Norman and Dr Ruth Griffiths An extensive survey of the mentally normal as well as the mentally abnormal has been initiated, and when the Trust eventually publishes its final report, it is hoped and expected that much valuable information will be forthcoming as to the nature of the transmission of mental abilities and disabilities The Trust has also arranged for the co-operation of other distinguished investigators from different parts of Great Britain, one of whom—Dr Shepherd Dawson of Glasgow—has already complied with the request of the Committee

Vital Statistics for 1934

THE provisional figures of the vital statistics for the year 1934 have been issued by the General Register Office, Somerset House They are as follows for England and Wales live births, 14·8, and deaths (crude rate), 11 8 per 1,000 resident population, and infant mortality rate (deaths under 1 year per 1,000 registered live births), 59. The birth rate shows an increase of 0·4 per 1,000 above the low record of 1933, and is noteworthy as being the only increase recorded since 1920, except in 1928, when there was a slight improvement of 0 1 following an exceptional fall in the previous year The crude death rate is 0·5 below that for 1933, and only 0 4 above the lowest recorded in 1930 The infant mortality rate is 5 per 1,000 below that for 1933, and is the lowest recorded, the previous lowest being 60 for 1930

Scientific Exhibition at Bombay

THE staff and students of the Royal Institute of Science, Bombay, held a most successful Scientific Exhibition on December 13–18, 1934, in aid of the Bombay hospitals. In a country like India which possesses few scientific museums, such exhibitions have great educational value, and the example of the Bombay Science Institute might well be followed elsewhere. About a thousand pounds were realised for the hospital fund. It may be remembered that similar exhibitions were organised in London several years ago in connexion with the King Edward's Hospital Fund and were very successful

Solid and Liquid Gases in Science and Industry

THE low temperature exhibition, which is being arranged by the Science Museum, has already been mentioned in these columns, we now learn from the director of the Museum, Col E E B Mackintosh, that the opening date has been postponed until March 1936 in order to give a longer time for the preparation of the exhibits The exhibition will remain open until the end of May and will therefore immediately precede the Seventh International Congress of Refrigeration to be held in Holland in May 1936 Promises of several interesting exhibits have already been received and the committee, under the chairmanship of Mr H T Tizard, has made considerable progress with the arrangements The other members of the committee are Dr Ezer Griffiths, Prof P Kapitza, Prof F A Lindemann, Prof J C McLennan, Lord Melchett, Mr C C. Paterson, Dr J D Pollock, Prof F Simon, Prof M W Travers and Mr R S Whipple, while the Museum officer responsible for carrying out the arrangements is Mr T C Crawhall, who was also responsible for the Refrigeration Exhibition recently held in the Science Museum

Standardisation of Hospital Equipment

A COPY of a report made by a Committee set up in 1931 by the Public Health Congress Council, 13 Victoria Street, London, S W 1, to explore possibilities of standardisation of hospital equipment in Great Britain has been forwarded to county and county borough councils by the Ministry of Health (Circular 1410) It is concluded that some 30 per cent of the total maintenance costs of hospitals is incurred in respect of goods that can be readily standardised, without affecting the efficient working of institutions or interfering with the requirements of their professional staffs It is shown that by standardisation and bulk purchasing, economies of 10–30 per cent may be effected Standardisation is applicable to hospital furniture and textiles, crockery, cutlery, surgical materials and rubber goods, office requisites and many other articles , examples are given of economies that can be effected in this way, and reports of committees that have considered the subject in Germany and in New York are given in appendixes

New Map of Hispanic America

IN 1920 the American Geographical Society began the compilation of a map of South America from existing sources. The available material is considerable, but so far no general map had been produced in any sense representative of the existing information. The Society now announces the publication of fifty of the hundred and two sheets which together will cover America from Mexico to Tierra del Fuego. Already large blocks including most of Chile and much of Brazil are ready. The scale is 1 : 1,000,000 and the style is in conformity with the International Map of the World on that scale. The Society also announces

the publication of a catalogue of the maps of Hispanic America in four volumes, giving a complete list with critical notes of all the source material used in the compilation of the map

Announcements

It is announced in *The Times* of January 25 that the Loder Cup, awarded for "meritorious service in the cultivation and preservation of New Zealand flora", has been awarded to Lord Bledisloe who, during his term of office as Governor General of New Zealand, has done much for the protection of forests and encouraged the cultivation of the native flora

Lord Hirst of Witton has been elected an honorary member of the Institution of Electrical Engineers The thirteenth award of the Faraday Medal of the Institution has been made to Dr F B Jewett, president of the Bell Telephone Laboratories, New York The Faraday Medal is awarded not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution

"In order to bring to the notice of those interested in the applications of physics to the development of industry, to assist those engaged in industrial research and generally to promote the application of physics to industry" the Institute of Physics is arranging conferences on industrial physics A conference on "Vacuum Devices in Research and Industry" will be held in Manchester on March 28–30, under the presidency of Prof W L Bragg Membership of the conference is open to all interested, and there is no fee At the University there will be an exhibition of instruments, apparatus and books Further information can be obtained from the Secretary, Institute of Physics, 1 Lowther Gardens, Exhibition Road, London, S W 7

The Faraday Society will hold a general discussion on "The Structure of Metallic Coatings, Films and Surfaces" at the Imperial College of Science and Technology, London, S W 7, on March 29 30 An introductory paper will be read by Dr C H Desch The discussion will be divided into two parts Part 1 will be on "Electron Diffraction Methods" Prof G P Thomson will read a paper on "An Apparatus for Electron Diffraction at High Voltages"; Prof G I Finch is to deal with "Electron Diffraction and Surface Structure", and papers by several foreign visitors will follow The second part of the discussion will be on "The Structure of Metallic Coatings" Prof E N da C Andrade will read a paper on "The Crystallisation of Thin Metal Films", and papers by distinguished workers at home and abroad are promised Further information can be obtained from the Secretary, Faraday Society, 13 South Square, Gray's Inn, W.C 1.

The Institute of Chemistry will celebrate its charter jubilee this year. The Institute was founded in 1877, and incorporated by Royal Charter in June 1885 Arrangements are being made for a banquet to be held on July 9 and a reception on the following evening

A David Anderson-Berry Gold Medal, together with a sum of money amounting to about £100, will be awarded in July 1935 by the Royal Society of Edinburgh to the person, who, in the opinion of the Council, has recently produced the best work on the nature of X-rays in their therapeutical effect on human diseases A similar award will be made every three years

The Dobree collection of European Noctue which has been in the Museum at Hull for many years, and a catalogue of which (Pp. xv + 156 1*s.*) was issued in 1909, contained a certain number of type specimens In the interests of students of entomology, it seemed desirable that these types should be in the national collection, and arrangements have been made whereby they are now in the British Museum (Natural History) at South Kensington, which has supplied suitable specimens to take their places at Hull

Applications are invited for the following appointments, on or before the dates mentioned:—An engineer at the Fuel Research Station, East Greenwich—The Establishment Officer, Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S.W 1 (Feb 6). A borough electrical engineer for Middlesborough—The Town Clerk, Municipal Buildings, Middlesborough (Feb 11) A physiological chemist at the Imperial Institute of Agricultural Research, Bangalore—The High Commissioner for India, General Department, India House, Aldwych, London, W C 2 (Feb 15) An assistant in the Essex Museum of Natural History—The Principal, West Ham Municipal College, Romford Road, E 15 (Feb 15). Assistant electrical engineers in the Admiralty Service—The Secretary to the Admiralty (C E Branch), Whitehall, London, S.W.1 (Feb. 16) Assistants in clinical pathology, morbid anatomy, bacteriology and pathological chemistry in the British Postgraduate Medical School, Ducane Road, Hammersmith, W 12—The Dean (Feb 18) A lecturer in biology at Whiteland's College, Putney, London, S W 15—The Secretary (Feb. 20). A lecturer in chemistry in the Leicester College of Technology —The Registrar (Feb. 22) A professor of chemistry in University College, Exeter—The Registrar. A lecturer in natural history in the Froebel Educational Institute, Grove House, Roehampton Lane, S W.15—The Principal A Cargill professor of applied physics in the University of Glasgow—The Secretary to the University Court. A Gardiner professor of physiological chemistry in the University of Glasgow—The Secretary of the University Court. An assistant research engineer at the B.B.C.—The Chief Engineer, Broadcasting House, London, W.1. A temporary assistant lecturer in mechanical engineering at the Gloucester Technical College—The Principal.

Letters to the Editor

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Origin of the Cosmic Rays

FROM the properties of the kinematic world-models which I have been investigating during the past two and a half years, it can be shown that any unimpeded free particle, at large in inter-galactic space, undergoes acceleration as reckoned by an observer located on any arbitrary nebula, and attains the speed of light at some finite epoch in the experience of that observer. It then decelerates It can also be shown that at any arbitrary epoch, in any arbitrary domain of inter-galactic space, there will occur some particles possessing velocities arbitrarily close to that of light. If such a particle, of atomic dimensions, happens to undergo a collision during this phase of its trajectory, it will give rise to effects similar to those observed in cosmic ray experiments I therefore identify the primary agency responsible for cosmic rays with high-speed particles accelerated to the vicinity of the speed of light by the gravitational pull of the rest of the universe[1]. The arguments required are purely kinematical, and involve no appeal to any specific theory of gravitation, or any arbitrary hypotheses

This identification is compatible with the corpuscular character assigned to the primary agency by many authorities The identification accounts for the observed isotropy, and it provides the origin of the high energies, predicting indeed that there is no upper limit to the energy of a single 'ray'. The energy is drawn from the infinite energy associated with the infinitely many particles constituting the universe. Lastly, the identification removes the old impasse to which other theories of the origin of cosmic radiation have appeared to lead. that if the primary rays were born in the interiors of stars, it is difficult to see how they could ever get out, yet if they were born as a result of multiple collisions in inter-galactic space, it is difficult to see how the inter-galactic density of matter could be high enough.

A full account of these investigations will appear shortly in a volume to be published by the Clarendon Press. The results were first described at Dr. N. V. Sidgwick's colloquium at Oxford on February 19, 1934, and have been discussed in numerous lectures elsewhere.

'Extra' Rings and Bands in Electron Diffraction Patterns

SO-CALLED 'extra' or forbidden rings have been observed from time to time in electron diffraction patterns, and their origin has been attributed to half-order diffractions or impurities. Cases in which more than one such ring have occurred in a single pattern have been rare. We have obtained patterns from platinum, gold, silver, cobalt, nickel, chromium, iron, tin, graphite and zinc oxide exhibiting not only up to as many as 14 'extra' rings, but also remarkable circular bands with well-defined heads

The main facts relating to these rings and bands, so far as they have been ascertained, are as follows: (1) The method of production of the specimen is immaterial, but the crystals must be orientated; (2) specimens of similar thickness and method of preparation show much less background if the crystals are orientated than when randomly disposed, (3) for a given orientation the 'extra' ring and band pattern is characteristic of the crystal lattice, for

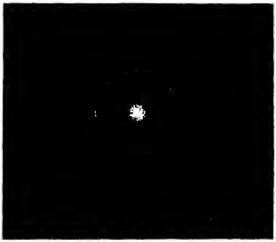

FIG 1

example, all body-centred cubic polycrystalline films with (111) face orientation yield 'extra' rings in the same relative positions, (4) no 'extra' spots have been observed in single crystal patterns, (5) with a suitable film, the thickness being rather critical, a pattern consisting almost wholly of 'extra' rings can be obtained, finally, (6) one head of each band coincides with a normal ring or with the central spot, while the other consists of an 'extra' ring. Fact (1) excludes impurity as a contributory factor, and (5) suggests that secondary scattering plays no material rôle in the formation of 'extra' rings; indeed, it can be shown that a primarily diffracted ray, *hkl*, on undergoing a second scattering, *h'k'l'* in the same crystal will give diffracted rays falling on normal pattern rings.

It seems to us that the 'extra' rings and bands owe their origin to the external crystal shape, that is, to the boundary faces through which the electron beam leaves the crystals. For example, the pattern, Fig. 1, was obtained from a face-centred cubic polycrystalline silver film orientated with 110 planes normal to the beam, that is, equivalent to a single crystal rotating about an axis in the beam parallel to a cube-face diagonal. Four distinct 'extra' rings lie within the very intense 111 ring, and two conspicuous bands are

visible, one between the central spot and the first 'extra' ring and the other between the 200 and the outermost 'extra' ring just inside the 111. The first, third and fourth 'extra' rings correspond to diffraction of the primary beam by plane gratings consisting of the atoms in the (111) exit faces, while the second and also the fourth correspond to diffraction by (120) exit planes. As the electron wave fronts pass down the inclined exit faces, the third Laue condition and the structure amplitude restrictions relax and finally disappear, with the result that one intense band is swept out between the 200 and the fourth 'extra' ring and another between the central spot and the first 'extra' ring. A similar explanation has been found to account for the other bands and 'extra' rings so far observed.

The value of the 'extra' rings and bands in crystal structure analysis is evident. We have here for the first time a possible means for identifying the actual crystal faces in crystals of sub-microscopic dimensions.

Differences between Male Hormone Extracts from Urine and from Testes

THE identity of the male hormone, extracted respectively from urine and from testes, has been assumed but never proved since the original isolation

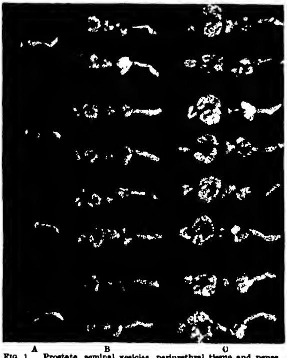

FIG. 1. Prostate, seminal vesicles, periurethral tissue and penes of rats. A, controls; B, treated with urinary extract; C, treated with testis extract.

of active substances from these two sources. We[1] and also other authors[2,3] have pointed out various chemical and biological differences. The following experiment shows a more definitive differentiation.

Twenty-one male rats were castrated when 3–3½ weeks old, and at the age of 6–6½ months, when the average weight was about 260 gm., were divided into three groups. The first group of five animals was untreated. The second group of eight animals received injections of male hormone extracted from urine; the third group of eight animals, injections of male hormone extracted from testicles.

The extracts were administered during four periods of six days, the dosage being increased at each phase. The preparations had been standardised on capons. During the first six days, 2 × 0.5 comb units (C.U.) daily were given; during the second six days, 2 × 1 C.U.; during the third six days 2 × 2 C.U.; and during the fourth six days 2 × 4 C.U. When the animals were killed on the day after the last injection, they showed extraordinary differences in the size of the seminal vesicles (Fig. 1). The average weight of the seminal vesicles was 8 mgm. in the controls, 113 mgm. in the group treated with urinary extract and 538 mgm. in the group treated with testicular extract. The difference in size of the prostate of the injected animals was much less (6 mgm., 66 mgm., 105 mgm.). The histological findings are to be published later.

Excretion of Nitrogenous Compounds from the Root Nodules of Leguminous Plants

THE activities of the nodule, and particularly the excretion of nitrogenous compounds from the nodule into the medium, are largely dependent upon the supply of air to the roots. The quantity of excreted nitrogenous compounds is the greater the larger the culture flask. This fact has been clearly demonstrated by our experiments with sterile cultures of inoculated peas in quartz sand. The results also showed that the rate of excretion is proportionally highest at an early stage of development of the plants when the nodules are still quite young. Hence it can be concluded that the passage of the nitrogen compounds into the sand actually is due to excretion and not to a decomposition of the nodule proteins.

We have previously shown[1] that nitrogen compounds, found in sand after growth of inoculated leguminous plants under sterile conditions, consist mainly of amino-acids. Since these compounds cannot be breakdown products of nodule proteins it is reasonable to assume that the fixation of nitrogen takes place at the surface of the bacterial cells in the nodule, and that nitrogen compounds thus formed are partly utilised by the host plant and partly diffused into the soil. This view receives additional support from the fact that the proteoclastic action of leguminous bacteria and nodules is very slight.

Excretion of nitrogenous compounds from root nodules is not attributable to a mechanical wounding of the root hairs through sharp-edged sand particles, since the same phenomenon was found to

take place also in agar cultures if the access of air to the nodules and roots is facilitated by allowing the agar to shrink. Consequently, the excretion is a natural process which is closely dependent on the air-content of the medium.

Recently we have found[2] that pea and clover nodule bacteria effect a butyric fermentation of glucose, whereby hydrogen is also produced. This finding will probably help us to gain a clearer conception of the mechanism of nitrogen fixation. All attempts to effect a fixation of nitrogen by free living nodule bacteria have so far led to negative results. This is probably due to the fact that ordinary sugar compounds are very poorly utilised by these bacteria. It seems, therefore, natural to assume that the nodule bacteria receive from their host plant some particularly suitable sugar compound which is readily utilised, and provides the energy required for nitrogen fixation. Theoretically it would thus be possible to effect a fixation of nitrogen by free-living nodule bacteria as soon as the chemical nature of the specific carbohydrate is ascertained.

Further details will be published in the *Journal of Agricultural Science*.

Synthetic Compound with Vitamin B_2 Activity

ACCORDING to a note[1] in NATURE on a lecture recently given by me, synthetic 6.7-dimethyl-9-1-araboflavin, $C_{17}H_{20}N_4O_6$, possesses similar growth-promoting activity to that of lactoflavine (vitamin B_2). The statement, that a catalytically active compound results by combination with the colloidal carrier of the 'yellow enzyme' of O. Warburg and W. Christian is incorrect, both for the natural and synthetic pigment, in so far as experiments *in vitro* are concerned. According to the *in vitro* experiments described by H. Theorell[2], phosphoric acid plays an important rôle in the combination. *In vivo*, on the other hand, a combination of both pigments with phosphoric acid and protein to form yellow enzymes apparently takes place. *In this sense only*[3] does the synthesis of a compound with vitamin B_2 activity represent also the first synthesis of the active group of an enzyme.

Formulæ and Equations in Nuclear Chemistry

THE question which Prof. Lowry raises on p. 36 of NATURE of January 5 is one which has perforce exercised my mind in the last few days, since I am at present revising the final page-proofs of the report of the International Conference on Physics. He refers to the different positions in which the numerals indicating the mass and atomic number of a nucleus are placed by different writers. Thus, we have ${}^4_2He$, ${}_2He^4$ and He_2^4. He points out that if the last form is used, there is a difficulty in showing the number of atoms in a molecule in the customary English fashion (for example, Cl_2) whilst both the second and third forms introduce a difficulty for the French chemist, who is in the habit of writing Cl^2 for a molecule of chlorine.

As a matter of fact, the ideal symbolism would leave space not only for this numerical indication, but also for a sign to denote the state of ionisation. The two requirements together completely rule out both the second and third forms above, leaving only the first as suitable for general adoption.

From a logical point of view, if the symbol refers to a nucleus and not to a complete atom, the lower numeral is unnecessary. If a nucleus has subscript 2, it is helium, and conversely. Thus, the simplest method would be to write ${}^4He$, ${}^6Li$ or ${}^7Li$. The only objection is the ugliness of the juxtaposed large and small figures in such an equation as $2{}^1H_2 + {}^{16}O_2 = 2{}^1H_2{}^{16}O$.

If we were bold enough, we should adopt a logical scheme, and save the printer much trouble, by giving up the letter instead of the subscript. An atom would be represented by a number or numbers in a bracket: (1, 1) and (1, 2) for ordinary and heavy hydrogen, (2, 4) for helium, (3) to mean either isotope of lithium, and so on.

The above reaction would then be written

$$2\,(1,1)_2 + (8,16)_2 = 2\,[(1,1)_2(8,16)]$$

It is easy with this notation to show states of ionisation. $(17,35)^- + (19,39)^+ = [(19,39)\,(17,35)]$ or $(17)^- + (19)^+ = [(19)\,(17)]$ would replace the familiar $Cl^- + K^+ = KCl$.

If it is decided to retain the use of letters, I would plead for the use of H to signify all the isotopes of hydrogen. When H is restricted to mean ${}^1_1H$, we have the additional symbols ${}^2D$ and ${}^3T$ (with perhaps ${}^4Q$ to follow) to remember, and there is no symbol available to mean hydrogen in general. One is certainly needed for this purpose, and the need is illustrated on p. 23 of the issue of NATURE to which I have already referred.

Absorption Spectrum of Sulphur Monoxide

IN a recent investigation[1], we attempted to detect sulphur monoxide in the photochemical decomposition of sulphur dioxide by examining the absorption spectrum of the latter before and after its irradiation. An absorption spectrum of the monoxide was reported to have been found by P. W. Schenk and H. Cordes[2] in the spectral region between 3300 A. and 2500 A., and although sulphur dioxide has very strong absorption bands in this region, they found evidence of the spectrum of sulphur monoxide, even when its concentration was 10^4 times smaller than that of the dioxide[3]. This spectrum, however, could not be detected in the photochemical decomposition of sulphur dioxide, and it has been assumed[1] that the act of photo-dissociation provides sulphur monoxide with a surplus amount of energy which makes it react instantaneously. But since this surplus amount of energy is only 13 cal. for 1950 A., this conclusion did not seem quite satisfactory. It seemed advisable,

therefore, to ascertain whether the absorption spectrum described by Cordes and Schenk was to be attributed to the presence of the monoxide.

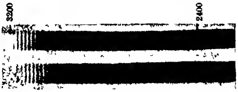

FIG 1 Absorption spectrum of sulphur dioxide, (a) before, and (b) after discharge.

An electrodeless discharge was produced in sulphur dioxide and the absorption spectrum was taken before and immediately after the discharge, as shown in Fig 1 The intensity of the spectra is not quite the same, for a thin sulphur film had partly covered the plate during the $2\frac{1}{2}$ hours of discharge, and it seemed necessary to take a longer exposure. Nevertheless, in spite of the difference in intensity, the identity of the two spectra cannot be doubted, so that there is definitely no new absorption spectrum produced by the discharge That is quite clear in the original plate, but naturally not so clear in the reproductions. The presence of sulphur monoxide, on the other hand, in the discharge is proved by its emission spectrum, taken during the discharge (Fig 2), which shows the same bands as the spectrum that was analysed first by V Henri[4] and later by E V. Martin[5]

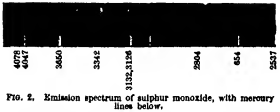

FIG. 2. Emission spectrum of sulphur monoxide, with mercury lines below.

It seems necessary, therefore, to ascribe the absorption spectrum found by Cordes and Schenk to some product of the discharge other than sulphur monoxide, in other words, our experiment indicates that sulphur monoxide in small concentrations has no absorption spectrum between 3100 and 2500 A.

Sources of Error in Absorption Spectroscopy

IN studying the absorption spectra of the vapours of the homologous aldehydes[1] a band spectrum was observed in butyric and *iso*-butyric aldehydes, which was ultimately discovered to be due to benzene. Inquiries showed that the catalyst used in the preparation of the aldehydes had been washed with benzene, thus accounting for the presence of an aromatic impurity which would not normally be expected to occur in aliphatic compounds. The spectrum is, however, so intense that, when the observation tube had been used to secure a comparison spectrum of benzene, it was very difficult to get rid of this spectrum in subsequent exposures

In attempting to photograph the fine structure of acetone, Dr. F C Garrow in 1931 observed a very fine series of bands, corresponding in general character with those recorded by Bowen and Thompson[2], which Norrish, Crone and Saltmarsh[3] and Noyes, Duncan and Manning[4] have not been able to reproduce. The bands observed by Dr Garrow were, however, due to interference, since they were only slightly weakened when the tube was empty, they were also observed with a single end plate, and were only got rid of by using other quartz plates Bands of a similar character have been described by Schaeffer and others[5], and those now recorded are probably similar in origin The occurrence of a few weak bands at wave-lengths less than 2900 A has already been recorded by us[1], but no trace of a genuine fine structure could be found in this region

Properties of Liquid Films in Fine-Pored Systems

THE properties of liquids, and in particular of water, when held by finely porous material, are of interest to workers in both the pure and applied fields A growing mass of evidence points to the necessity of assuming a modification in properties of such liquid films even in thicknesses corresponding with many molecular layers.

Shereshefsky[1] and others have produced definite evidence that measured vapour pressures of liquids in small capillaries (of radius 0 0005 cm. and less) are very much smaller than those calculated from the Kelvin equation. In view of this result, it is interesting to note that experiments at the Building Research Station, shortly to be published, have shown that for several finely pored plastic materials, the hydrostatic suction necessary to remove water is of quite a different order from that which would be expected from the vapour pressure relation. Similar anomalous behaviour has been found when the same moist plastic materials are brought to equilibrium with a solution of sugar of known osmotic pressure through a semi-permeable membrane. Calculations show that large discrepancies also exist in published literature, where it is possible to compare sets of determinations by two dissimilar methods. Thus Szigeti's[2] measurements of vapour pressures and negative absorptions from sugar solutions show these anomalies.

Among other cases of anomalous behaviour reported which may be due to the same causes the following may be noted: Glixelli and Wiertelak[3] found low values for the electro-kinetic potential in

silica gels which became normal in ignited gels White, Urban and Van Atta[4] found very low values for stream potentials in pyrex glass capillaries of less than 0·001 cm diameter. Wolkowa, in measuring the velocity of penetration of liquids into finely powdered materials, found regular behaviour with non-polar liquids but anomalous results with water and other polar liquids Measurements carried out at the Building Research Station of the dielectric constant of liquids in porous materials and its variation with frequency have been found to exhibit discrepancies which may prove to be related with observations on water in soils made by Smith-Rose[6]

It is suggested that Hardy's[7] conception of molecular orientation in thin liquid films formed on the surface, for which strong evidence is afforded by their behaviour as lubricants, may provide a means of reconciling the anomalies to which we now direct attention In such films, the work required to tear up 'by the roots' orientated chains of molecules, as is necessary in molecular exchanges between film and gaseous phase or across a semi-permeable membrane, may be much greater than that required to slide layers from the surface in a manner which may be considered to occur when a direct hydrostatic suction is applied This crude picture is, of course, open to objections which it is not possible to discuss here, but it may serve to emphasise the desirability of carrying out measurements by two or more different methods in any studies designed to further our knowledge of the capillary properties of liquids in finely porous systems

Galvanometer Relays

THE use of the rectifier photo-cell to amplify galvanometer deflections is now well known; but I have never seen any explicit mention of the fact that, with the customary set-up[1], the deflections of the second galvanometer are not in general proportional to those of the first. The discrepancy arises because the area of the photo-cell illuminated changes as the deflection of the primary galvanometer changes

I am now using a modified system in which this defect is absent. The beam of light from the primary galvanometer mirror forms a rectangular image on a lens, immediately behind which is a pair of right-angled prisms, which throw part of the light on to one cell and part on to another. The lens forms an image of the galvanometer mirror on each cell. As the rectangular image moves across the lens more light is thrown on to one cell and less on to the other: but there is no change of the cell area illuminated in either case, the only effect being to vary the brightness of the images on the cell surfaces Thus, non-uniformity of the sensitivity of the surfaces cannot affect the proportionality between the deflection of the two galvanometers.

The two cells are connected across the galvanometer in parallel with, and in opposition to, each other; this method of connexion gives considerably greater amplification than can be obtained with a divided cell of the same photo electric sensitivity.

Addition of Hydrogen Bromide to Olefines

THE results of several investigations have confirmed the discovery[1] that oxygen and peroxides ('oxidants') may greatly affect the addition of hydrogen bromide to olefinic substances[2] In all these investigations the double-bond has been in the terminal position ($CH_2 = CH - CH_2 -$), oxidants causing the addition of hydrogen bromide to yield $CH_2Br - CH_2 - CH_2 -$, and 'anti-oxidants' allowing the formation of $CH_3 - CHBr - CH_2 -$.

In order to ascertain whether the same effect could be produced in the reactions of an olefine containing a non-terminal double-bond, we have studied additions to *iso* undecylenic acid[3] ($CH_3 - CH = CH - (CH_2)_7 - COOH$) This olefine adds hydrogen bromide relatively slowly, and yields the same proportions of 9- and 10-bromoundecoic acids, whether oxidants or anti-oxidants are present As undecylenic acid ($CH_2 = CH - (CH_2)_8 - COOH$) clearly shows the peroxide effect (Ashton and Smith, loc. cit) there is now some evidence that only terminal double-bonds are susceptible

Ionisation of the Kennelly-Heaviside Layer

THE eclipse observations of August 31, 1932, and Appleton's Tromsø observations, indicate fairly certainly that the normal daytime ionisation in the *E* layer (100 km. height) is due mainly to solar wave radiation, and not to neutral corpuscles as Chapman suggested. But the ionising wave radiation may not be ultra-violet light (in amount corresponding to Planck's formula at the sun's temperature) as now generally supposed. As Eckersley has remarked, if the ionising agent is wave radiation, it must be so penetrating as to be of Röntgen type; but he disbelieves in the emission by the sun of an adequate amount of such radiation (Elias, however, for a time considered such rays to be the cause of the *E*-layer).

But solar conditions seem not to preclude such radiation. If, as Swann has suggested, very fast electrons are produced in sunspots, most of them

must lose their energy again in the photosphere and chromosphere, and in so doing will excite Röntgen radiation, both continuous, scattered and characteristic The emission need not be confined to sunspots Bartels' M-regions show that important solar phenomena can still remain undetected by us

The mass-absorption coefficient (μ/ρ) of ultra-violet light is too great for this to penetrate to 100 km height Too little is yet known about the value of μ/ρ for light between the ultra-violet and the Röntgen region, systematic measures using the Hopfield continuous spectrum of helium are very desirable For ultra-soft Röntgen radiation, the course of the μ/ρ curve is known approximately to $\lambda = 68$ A, for which wave-length Messner recently found $\mu/\rho \sim 1\ 46 \times 10^4$ At 700 A, μ/ρ is certainly much greater, probably similar to that of celluloids, for which O'Bryan found a maximum for μ/ρ ($5\ 8 \times 10^4$) at 800 A Probably Hulbert's estimate ($\mu/\rho \geqslant 8\ 8 \times 10^5$) of μ/ρ for ultra-violet ionising light is truer than that used by Försterling ($1{\cdot}2 \times 10^5$)

The height of maximum ionisation depends essentially on μ/ρ If $\mu/\rho = 5{\cdot}5 \times 10^5$ (ultra-violet light), the height at midday must exceed 130 km if the air temperature T is 218° K, and a lower value of T has not been proposed This assumes no diffusive separation of the separate gases if this occurs, the height might be 4 km lower It would exceed 200 km. if the outer layers consist of atomic oxygen as suggested by Chapman Again, the fact that the gases of the atmosphere have absorption *bands* in the ultra-violet implies that the thickness of the absorbing layer must much exceed that of the ionised layer (scarcely 30 km.) Hence ultra-violet light is unlikely to be the ionising agent for the E layer, unless its value of μ/ρ has been over-estimated a hundredfold.

We are thus led to conclude that the agent is Röntgen radiation According as T is taken to be from 218° to 323° K. (and it cannot exceed 100° C. in the E-layer), the Röntgen wave-length will lie between 13 A and 3 5 A., and also, on account of the K absorption limit of nitrogen at 31·1 A, from 40 A to 31·1 A. As regards the characteristic radiations that may be involved, we may note the K-radiations from Na (11) to Ca (20), the L-radiations of Ca and those from Cu (29) to Sn (50), and the M-radiation from Ce (58) to U (92). The soft series for the elements near iron can be of importance only if $T < 218°$ K.

Eocene Beds of the Punjab Salt Range

MR. E. S. PINFOLD and I have recently made a special examination, on behalf of the Attock Oil Company, of the Eocene beds of the Punjab Salt Range, with the view of determining their exact age. It will be remembered that opinions as to this have varied greatly in the past, some geologists referring them to the Laki, others to the Khirthar, while others again have shelved the question of their precise age by calling them "Hill" limestones or "Nummulitic beds", etc.

I have now found, on examining fossils collected from these Eocene beds by Mr. Pinfold, that the beds are actually divisible into two distinct portions, the lower one belonging to the Ranikot and the upper to the Laki Having lately received permission from the Attock Oil Company to publish our results, Mr Pinfold and I hope shortly to produce a paper in which the relevant field and palæontological evidence will be discussed in detail.

"The Horizons of Thought"

I KNOW that a reviewer's comments on a book, especially when published in an international journal, travel many leagues while an author's reply is getting into an envelope, but for all that I would ask you to allow me to comment on your reviewer's words (in NATURE of October 20, 1934, p. 617) concerning my book, "The Horizons of Thought". I am surprised to read that there is a "peculiar method" employed in the book; the reviewer seems to imply that it is a superficial eclecticism, which of course no one could countenance As a matter of fact, the quotations are used for illustration and application of principles previously worked out and published in preliminary form elsewhere, as indicated in the preface The reviewer seems to complain because contexts are not stated; they are omitted for the sake of brevity, and also because I was interested not so much in contexts as in contacts and conflicts with the principles worked out. I was interested not so much in elaborating my perhaps "general and obvious", and perhaps even "more or less relevant" conclusions, as in showing how often in contemporary thought their principles are disregarded, with consequences all the way "from mathematics to ethics". Finally, I must disclaim the wish which the reviewer imputes to me, of solving problems which lie beyond the horizons I think the primary task of philosophy is to work within the island-universe of the sciences (logical, mathematical, natural and social), and treat a great mass of traditional outlying questions non-committally.

GEORGE P CONGER
Department of Philosophy,
University of Minnesota,
Minneapolis, U.S.A
Dec 5

I AM interested in Prof Conger's letter, and I understand his points clearly. To deal with them satisfactorily would, however, occupy more space than could reasonably be asked for in NATURE; and I do not think a controversy on these subjects would serve any practical purpose

THE REVIEWER.

Symbols for Chromosome Numbers

I AGREE with Miss Schafer[1] that the use of a Greek letter for the basic chromosome number has serious disadvantages and should therefore be dropped. But I think a new symbol is necessary, to avoid the confusion which results from a resuscitation of x for this purpose. This symbol tends to be overworked, presumably because every schoolboy begins his algebra with x as the unknown quantity. In the result we have papers written on the effect of X-rays on the X-chromosome, In this case, however, no confusion results, because the two uses of X are so different.

Formerly x and $2x$ were in universal use for the haploid and diploid chromosome numbers. Since then, usage has gradually shifted to n and $2n$, presumably to avoid confusion with X, which began, after 1900, to be used for the sex chromosome, but x and $2x$ are still employed to some extent in the original sense, as previously pointed out[2], so three uses of the symbol in relation to chromosomes have to be distinguished.

In these circumstances, and in view of the place x has already had in the nomenclature of chromosomes, confusion can only be avoided by adopting a new symbol for the new conception, and I suggest b as a suitable symbol for the basic number

Since this was written, I find that b as a symbol for the basic chromosome number has already been proposed by Sinotô[3]

Miss Mirsky's "Northern Conquest"

IN my review of this delightful book I was wrong in making it appear on p 884 of NATURE for December 8 that the work was done under the critical supervision of Dr Stefansson I now know that this was not the case The great explorer did not see the book until it was submitted to him in a complete form by the publisher Miss Mirsky is thus entitled to all the credit for her brilliant work

In mitigation of my blunder, I can only say that, like the writer of the legendary article on Chinese metaphysics, I must have combined the information derived from two unrelated statements These were the phrases in Miss Mirsky's prefatory note (1) "During the three and a half years I spent on the book " and (2) " the generosity with which Vilhjalmur Stefansson placed his fine library at my disposal" Of course, I should not have inferred that the book was written in that library, the use of which only contributed to the compilation of the illustrative maps

HUGH ROBERT MILL

Points from Foregoing Letters

COSMIC rays are identified as particles accelerated to a speed near to that of light by the gravitational pull of the rest of the universe in the kinematic world model put forward by Prof. E. A Milne There is no upper limit to the energy that such a particle may acquire, since it is drawn from that of the whole universe

According to Dr G I Finch and Mr A G Quarrell, the 'extra' rings observed in certain X-ray diffraction patterns are due to the shape of the minute crystals that compose the materials investigated, and may therefore help in finding the shape of sub-microscopic crystals The ordinary X-ray diffraction rings are due, of course, to the lattice arrangement of atoms within the crystals

Male hormone extracts, obtained from testes and from urine, while possessing the same power of stimulating growth of combs on capons, are found by Messrs. E Dingemanse, J. Freud and E Lacqueur to differ in their effect upon the growth of seminal vesicles in castrated male rats. This shows that the urinary and testicular extracts used are not identical.

Prof. A I. Virtanen and Mr. S. v. Hausen point out that the nitrogen compounds (amino-acids) found in soil where leguminous plants are grown are excreted by the bacteria nodules of their roots and are not attributable to mechanical wounding of the roots, because it can be shown that excretion takes place also on an agar culture, provided access of air to nodules is facilitated. The authors have further discovered that pea and clover nodules containing bacteria can produce butyric fermentation of glucose, and they suggest that the bacteria are supplied by the plant with a suitable sugar, which provides energy for the nitrogen fixation More knowledge of this mechanism may lead to the discovery of the conditions necessary in order that the bacteria may fix the nitrogen of the air *in vitro*.

Dr. G. Kornfeld and M. McCaig find that small amounts of sulphur monoxide present in sulphur dioxide after an electrodeless discharge, can be detected by means of the emission spectrum, but not by means of the absorption spectrum, because the dioxide itself has strong absorption bands similar to those of the monoxide

Dr C P Snow and Mr E. Eastwood point out, as possible sources of error in determining the absorption spectrum of vapours, the possible presence of small amounts of impurities and the effect of interference bands due to the quartz plates of the apparatus.

Thin films of liquid such as may exist in finely porous materials have properties different from those of liquids in bulk Messrs B H Wilsdon, D. G R Bonnell and M E Nottage mention their lower vapour pressure, with which is related the greater hydrostatic suction needed to remove water from certain building materials Their osmotic pressure and electrical properties are also abnormal The authors point out that the behaviour of thin films may be connected with the fact that their molecules form more or less orientated chains.

Mr. D H Follett directs attention to the fact that at present, when a photo-cell is used to amplify galvanometer deflections, the amplified deflections are not proportional to the original. He describes an improved instrument avoiding this difficulty.

Neutrons and ultra-violet radiation have been suggested as possible agents responsible for the ionisation present in the electrically-conducting layers of the upper atmosphere which reflect radio waves Eclipse observations have ruled out the neutrons as active agents, while the ultra-violet radiation, from calculations by Dr E A. W. Muller, cannot penetrate in sufficient amounts as far as the E-layer (100 km. high). To account for that effect Müller assumes that the sun emits, in addition, a more penetrating radiation of the X-ray type.

The search for oil has supplied valuable information to geological science in the past. Lieut.-Col. L. M. Davies announces that an examination of the fossils from the early tertiary (Eocene) beds of the Punjab Salt Range in the sub-Himalayan zone shows that these strata belong to two distinct formations (Ranikot and Upper Laki).

Research Items

Discoveries at Troy. The long-awaited discovery of a cemetery at Troy is announced by Dr Carl Blegen, of the University of Cincinnati, in a communication issued by Science Service, Washington, D C This find was made by the third expedition of the University to Hissarlik. A second discovery of importance was on a site about three and a half miles from the actual citadel, at a marginal point of the area Here Dr. Blegen found four graves, apparently of neolithic age, containing skeletons which in his opinion belong to a period antecedent to any settlement hitherto found on the site and representing the earliest inhabitants. At the same point, but at a higher level, were later remains, dating from the time of the fourth and fifth layers of the citadel. The cemetery belonging to Troy itself was found just outside the citadel It is contemporary with the sixth city and consists of a series of urn burials containing ashes, remnants of burnt bones and traces of ornaments which had not been entirely consumed by the funerary pyres The practice of cremation burial, naturally and unfortunately, has destroyed all evidence of the physical characters of the inhabitants of the city. A further discovery among the ruined houses was that of a well-preserved buried floor, which affords the first opportunity here for the investigation of a habitation site The stone bases of columns which supported the upper story are still in place, but determining the alignment of the columns and the recovery of any household goods which the floor may have preserved will be the work of the expedition's next season

Glazed Stones in Antiquity. The first of a series of notes on glazed stones, dealing with glazed steatite, is contributed by Mr Horace C Beck to *Ancient Egypt and the East* (pt 2; 1934) The surface of steatite is found to have been altered by chemical processes due to at least three different methods of treatment The first was to apply a vitreous glaze to the surface and then fire it. This is true glazed steatite, and even when the whole layer of glaze is flaked away, a very hard surface is left on the steatite. A second method was to apply an alkali and fire it, or to apply a glaze of such a nature that when it is flaked away, it leaves a very soft surface on the steatite The third, perhaps a modification of the second, was to whiten the surface, probably with an alkali only and, after heating, to paint on a pattern. The effects of the various processes on the stone are different. All the Egyptian specimens of glazed steatite belong to the first class, and it is almost entirely an Egyptian product. It has been found extending in time from the Badarian period, being earlier than glazed faience, which does not appear until pre-dynastic times, down to the twenty-seventh dynasty The process was used extensively for beads, amulets and scarabs; but after the twelfth dynasty the beads are rare. There are a few very fine specimens of glazed steatite of considerable size, belonging for the most part to the period from the twelfth to the eighteenth dynasty. The beads with the best glaze are the Badarian. The seals from Mohenjo-daro and Harappa, some early seals of a similar nature from Kish and Ur and the great majority of the beads from Harappa belong to the second type, while the third type comprises only a comparatively small number of important beads from Harappa. An examination of six seals and several hundred beads from Mohenjo-daro and Harappa indicates that a different method was employed there from that used in Egypt, and it seems probable that more than one method was practised in the Indus valley

Phenological Observations in Great Britain. The "Phenological Report, 1933" (*Quart J. Met Soc*, 60, No. 255, 1934) deals as usual with facts relating to birds, insects and plants, such as the earliest date of arrival of a migrating species of bird, the earliest date of appearance of a particular insect or plant, supplied by voluntary observers distributed at more than five hundred places throughout the British Isles. The events recorded number more than sixteen thousand. This unwieldy mass of statistics is condensed and to some extent summarised with the aid of various tables and maps, and comparison between these and similar tables and maps in the reports for previous years will enable anyone interested in the natural history of the countryside to study the peculiarities of its seasonal course in this particular year. There is a sufficiently full meteorological summary to allow the influence of the weather in these matters to be gauged, and the year was remarkable enough for its deficient rainfall, its warmth and abundant sunshine to make it a good one for the pursuit of such studies. These reports must be of the greatest possible value for many branches of study, such, for example, as that of bird migration Average arrival dates for twenty species of bird for this year and for the seventeen years 1914–30 are shown side by side by means of lines of equal arrival date (isophenes) The extraordinary warmth of March and April 1933 in those regions from the south-west of Ireland across to Sussex and Kent where this date falls on average rather late in April, did not produce any notable departure from the normal, and in general normality appears to have been the rule. Autumn migrations, both incoming and outgoing, appear to have been decidedly early; no reason for this is suggested in the report It is interesting to learn that a phenological record has been maintained by one family at Hevingham (Norfolk) since 1736, with only one long break (1811–35). This establishes the average dates of arrival of the swallow, cuckoo and nightingale there as April 19, 25 and 26 respectively

Echiuridæ, Sipunculidæ and Priapulidæ of Scottish and Adjacent Waters. Dr. A. C. Stephen has investigated the distribution of the species of these groups in the Scottish area by examining collections made by the Fishery Board for Scotland in the North Sea and adjacent waters. The greater part of the material was taken with the small Petersen bottom sampler, and has come from all over the North Sea, from coastal waters to the edge of the continental shelf (*Proc. Roy. Phys. Soc*, 22, Part 4; 1934). *Priapulus, Sipunculus, Phascolosoma* and *Echiurus* are of economic importance for they serve as food for several food fishes such as plaice, lemon sole, common dab, witch, gurnard, whiting and haddock. Of these, *Priapulus caudatus* is by far the most frequently consumed, especially by haddocks caught in the

Firth of Forth and St. Andrews Bay; also in fish from the east coast of Scotland, Moray Firth and from over the North Sea. As many as ten specimens have been taken from a single plaice in the Cumbrae district, where it is generally distributed on muddy ground. In the North Sea more than 1,200 stations have been examined with the Petersen grab, and many hauls with other apparatus have been made. *Phascolion strombi* is the only species captured with regularity: the other species have been found at few stations and in small numbers, the reason apparently being, not that they are scarce, but that they burrow beyond the reach of the collecting gear. Little is known about the breeding periods or larval histories of these animals, but a few notes on the subject are given.

Earthworm Migrations. In his fourth paper on the earthworms of Burma, G. E. Gates (*Records Indian Mus.*, 35, Pt. 4, Dec. 1933) emphasises the need for the study of the extent of variation of the characters by means of which species are diagnosed and defined. He states that the lack of this information has resulted in the erection of unnecessary varieties and species, and that it is often difficult, if not impossible, to determine whether a particular individual or series of *Drawida* and *Eutyphœus* belongs to an old or a new species, and therefore it is imperative that the types of all old species be re-examined. In an interesting reference to migrations of earthworms, the author records an observation that "in the early morning on certain days in October and November at the beginning of the cold season the road is almost covered with worms, one can see worms tumbling down from the banks above on to the road. In the evenings not a worm is to be found. I have always assumed that the worms were moving down-hill perhaps in search of water". The author states that others who have been in the Chin Hills District during the same months reported that all the migrating worms were of the same kind and were all going down-hill. The specimens collected were all *Perionyx* (possibly *P. excavatus*) without clitellum.

Protozoan Parasites of Fishes. R. R. Kudo (*Illinois Biol. Mon.*, 13, No. 1, 1934) reports on a preliminary survey of the protozoan parasites of the fishes of Illinois. About 1,300 fishes belonging to 35 species and 13 families were examined, mainly for Protozoa attacking the tissues. The specimens of *Polyodon spathula*, *Lepisosteus osseus*, *Amia calva* and twenty-two other species were not infected but nine others belonging to the families Catostomidae, Cyprinidae and Siluridae were found to be common hosts of histozoic Protozoa, especially Myxosporidia, of which nineteen new species are described. In reservoirs near Peoria were observed large numbers of carp (*Cyprinus carpio*) suffering from an extremely heavy infection by a parasitic ciliate, *Ichthyophthirius multifiliis*. On the integument, gills and mucous membrane of the mouth cavity this ciliate was so numerous that the entire fish appeared whitish. In addition another ciliate, *Cyclochæta*, and a flagellate, *Costia*, were found abundantly in the lesions produced by the *Ichthyophthirius*, and the fishes appeared to be much weakened. *Ichthyophthirius* is world-wide in distribution and is often present in large numbers in fish kept in small aquaria, but it is unusual for such an epidemic to occur among fully grown fishes kept in large outdoor ponds.

A New Permian Fish. Mr. James Brough describes *Lekanichthys housei*, n.sp., a new dorypterid fish from the Permian (*Ann. and Mag. Nat. Hist.*, 10, 14, No. 81, Sept. 1934). The family Dorypteridæ has up to the present only contained *Dorypterus*. The new form displays many of the peculiarities of that genus, but shows clearly an intermediate grade of structure between the highly modified *Dorypterus* and the normal Palæoniscid. The type specimen, which is unique, was collected apparently many years ago, and has since lain in the Hancock Museum, Newcastle-upon-Tyne. It was unlabelled, but Mr. Brough has little doubt as to the horizon from which it was obtained, as both fossil and matrix possess all the characters of the Marl Slate (Lower Permian), particularly as it occurs in the south of Durham County, and the specimen was probably obtained from this stratum in the Middridge-Thichley Area. The fish is well preserved. Its general shape is similar to that of *Dorypterus*, showing specialisations of a like nature, but not developed to the same extent. In the characters in which it differs, it displays Palæoniscid affinities, and has therefore all the necessary qualities of a form ancestral to *Dorypterus* and intermediate in structure between it and the Palæoniscidæ, but, as the author states, this relationship is impossible since the remains are found in the same thin stratum, indicating that they lived side by side. He concludes that "*Lekanichthys* was a collateral ancestor—a form in the same group which either had evolved more slowly, or had reached a certain stage of specialisation and then halted, so that, although it is not a true ancestor, it reproduces the essential form of the ancestor at a certain stage".

Seasonal Variations of Carbohydrates in Fruit Trees. The second of a series of papers on "The Seasonal Cycles of Nitrogenous and Carbohydrate Materials in Fruit Trees" by members of the staff of Long Ashton Research Station (*J. Pomol. and Hort. Sci.*, 12, No. 4, pp. 249–292, December, 1934) deals with the seasonal cycles of alcohol-soluble materials, of carbohydrate fractions and lignin in the wood, bark and leaves of terminal shoots of apple trees. Two cultural systems are involved, namely, trees grown on grassland, with annual dressings of nitrate in spring, and trees grown on arable land, without nitrogenous fertiliser. It is the work of Dr. Elsie S. Smyth. Well-defined seasonal variations in the amounts of all the carbohydrate fractions were found, and changes in the wood and bark were similar. Difference in cultural treatment did not greatly affect the seasonal changes, though reducing sugars were rather more abundant in material from the arable plot in summer, than in trees grown on grass. There were also differences in starch content. Carbohydrate-nitrogen ratios were, however, higher in the trees grown on grassland, than in the arable crop. Variations in the contents of alcohol-soluble matter, in reducing sugars, sucrose, starch, hemicellulose, total carbohydrates, cellulose and crude lignin, are all set out in detail.

A 'Traversing' Microscope. An example of a travelling or traversing microscope has been submitted to us for examination by Prof. E. W. Scripture, by whom it was designed for the examination and measurement of ordinates of curves having a considerable area, such as are obtained by tracings produced by changes of air pressure at the mouth during speech. It consists of a large rectangular base-plate of thick plate glass in metal frame supported on feet, which

can be inclined if necessary so as to tilt it The microscope barrel is held by a carrier which can be moved by means of racks and pinion-screws, so that it traverses 145 mm. back to front along a transverse bar, and 545 mm. longitudinally along a longitudinal bar. The bars are graduated, and by means of verniers, readings to 0 01 mm can be taken The verniers are provided with lenses for reading, and are illuminated by small electric bulbs worked off a dry cell, and opaque objects may be illuminated by a bulb attached to the microscope tube near the objective For transparent objects, a sheet of white paper placed on the table beneath the base-plate usually suffices The objects to be viewed can be clamped to the base-plate by longitudinal or transverse adjustable bars, or kept in place by a piece of glass laid upon them While there is, perhaps, nothing very novel in design and construction, the instrument is noteworthy for the large area it can cover, and in addition to tracings is obviously adapted for the examination of large sections, membranes, fabrics, etc The instrument is well constructed in white metal, and was made by Messrs F. Homan, 13 Florence Road, S E 14

Organic Sulphur Compounds. A paper by Messrs F Challenger and J B. Harrison on sulphur compounds of technical interest, in particular the isomeric thiophthens, was read before a meeting of the Institution of Petroleum Technologists on January 8 Recently the occurrence of naphthalene, thiophen and thionaphthen in coal tar and Kimmeridge shale has led to the belief that thiophthen might also be an ingredient of similar substances, and the work undertaken on thiophthen and its derivatives and described in this paper was felt to be a necessary preliminary to proving or discounting that theory. Published technical data on those compounds are scanty Various methods of preparation of thiophthen are reviewed and a precise account of that of Capelle, which was employed in this case, is given In addition, notes are made on phenomena observed during reduction of solid thiophthen with sodium and alcohol and on the structure of the thiophthens as revealed by X-ray analysis Part of the paper is devoted to reports of various experiments undertaken and apparatus and methods employed These include purification of liquid thiophthen with mercuric chloride, preparation of liquid thiophthen with citric acid and phosphorus bisulphide, isolation of a by-product in the preparation of liquid thiophthen, oxidation and nitration of thiophthens, etc Accounts are also given of the preparation of certain derivatives of isomeric thiophthens

Cold Test for Fuels. Messrs B H. Moerbeek and A. C. Van Beest presented a paper on "Cold Test for Fuels" for discussion at a meeting of the Institution of Petroleum Technologists on January 8. Present methods of pour-point determinations of fuels were criticised and in particular the A.S T M. test was condemned on the grounds that results are dependent on the temperature at which the sample is pre-heated and on the thermal history of the batch of which it is part Furthermore, maximum and minimum pour-point figures are returned which may lie far apart, and thus cause confusion in the mind of the consumer The sensitiveness of residual fuels to their thermal history is attributed to the asphaltenes present, which are natural pour-point reducers, and experiments prove that their removal renders the fuel temperature-insensible. A new method of pour-point determination is therefore proposed which, it is hoped, will give more practical results To this end the influence normally exerted by asphaltenes is eliminated by pre-heating followed by pre cooling to such a temperature that the asphaltenes do not dissolve again Results are returned in such a way as to indicate a temperature at which fuel can be shifted under a fixed pressure The data collected as a result of these investigations are as yet insufficient to indicate whether the new method would be entirely satisfactory in practice; but there is enough information to arouse criticism and discussion of the principles involved

Colour Indices of Stars in Open Clusters. A number of plates of open star clusters were taken by Prof K Lundmark at the Mount Wilson Observatory in 1922–23, using the 60-in reflector with a wire grating placed in front of the mirror. These plates are now being measured by J M Ramberg, of the Lund Observatory, and a preliminary account of his results has just been published (*Lunds Medd.*, Ser. 2, No 70). A brief account of the theory of obtaining effective wave-lengths from coarse-wire grating spectra is given, together with a description of the methods used in measuring the plates and correcting the results for various sources of error The main object, however, was to standardise the measures for future work by comparing the resulting colour equivalents with the previously determined colour indices. For this purpose, five plates of Messier 37 were measured and the results correlated with colour indices by von Zeipel and Lindgren for stars in this cluster. The mean error of an effective wave-length was found to be $\pm$ 9 84 A., or $\pm$ 0 055 expressed in magnitudes. The final results are included in a catalogue giving the measured effective wave-lengths and calculated colour indices of 659 stars in Messier 37.

Nova Herculis. The *Observatory* of January publishes a summary of all further observations on this nova, which was discovered by Mr J P.M Prentice, of Stowmarket, on December 13, 1934 The editors of the *Astronomische Nachrichten* have also published supplements and numbers containing short accounts of observations, sent in by numerous Continental observers The nova when discovered had a visual magnitude of $2 \cdot 9^m$, after an initial decline, the magnitude rose to $1 \cdot 3^m$ on December 23. The brightness then declined sharply to $3 \cdot 4^m$ on December 26; it then increased very rapidly to $2 \cdot 6^m$ one day later Since then there have been more fluctuations. The nova has exhibited characteristic spectra, namely, emission lines and bands due to hydrogen, helium and ionised metals, especially when decreasing in brightness. On December 20, when approaching maximum, the nova showed a spectrum which corresponded line for line with α Cygni (type *cA2p*). On December 23, the only marked emission line was $H\alpha$. On the other hand, on December 30, when the brightness had declined, the continuous spectrum had nearly vanished, leaving a strong emission band spectrum. The nova has been identified with a star of magnitude $15 \cdot 4^m$ on the Franklin Adams plates There is some evidence to show that the star was a variable before the present outburst. An estimate of the star's distance, based on the intensity of the interstellar Ca+ lines, makes the distance 200 light years (a previous estimate was 2,000 light years).

Prize Awards for 1934 of the Paris Academy of Sciences

AT the annual public meeting of the Academy of Sciences the prize awards for 1934 were announced as follows:

Mathematics.—The Poncelet Prize to Maurice Fréchet for the whole of his mathematical work; the Francœur Prize to Jean Favard, for his work in mathematical analysis.

Mechanics.—The Montyon Prize to René Swyngedauw, for his studies on belts and ball bearings; the Fourneyron Prize to Robert Mazet, for his work on friction; the Henri de Parville Prize to Jean Leray, for his work on the mechanics of fluids.

Astronomy.—The Lalande Prize to Daniel Barbier, for his work on double stars; the Valz Prize to Ferdinand Quenisset, for his observations on comets; the Janssen Medal to Walter Sydney Adams, for his researches on stellar parallaxes.

Geography.—The Delalande Guérineau Prize to Jules Sion, for his work entitled "La France méditerranéenne"; the Gay Prize to Maurice Pardé, for his work entitled "Fleuves et rivières"; the Tchihatchef Foundation to Jean Gubler, for the publication of his work on the palæontology of Cambodia; the Binoux Prize in equal parts between Jules Schokalsky, for his memoir on the measurement of the lengths of rivers in Asiatic Russia, and Pierre Tardi, for his treatise on geodesy.

Navigation.—The Navy Prize to Jean Ottenheimer, for his work on ballistics and on submarine explosions; the Plumey Prize between René Anxionnaz (1,500 francs), for his work on internal combustion motors, André Chapelon (1,500 francs), for his work on the improvement of steam locomotives, and René Retel (1,000 francs), for his work on injection in Diesel motors.

Physics.—The L. La Caze Prize to Eugène Bloch, for the whole of his work in physics; the Kastner-Boursault Prize to Théodore Lehmann, for his work in electrotechnics and especially for his studies on tracing magnetic lines of force; the Hébert Prize to François Bedeau, for his "Traité de télégraphie sans fil" and for his researches on the methods of measurement with high frequency; the Hughes Prize to René Lucas, for his work in electro-optics; the Clément Félix Foundation to Marcel Laporte, for the continuation of his researches on the properties of the ions and on the electrical luminescence of gases.

Chemistry.—The Montyon Prize (Unhealthy Trades) to Paul Bruère, for his researches on individual or collective protection against poisonous gases or vapours; the Jecker Prize to Henri Hérissey for the whole of his chemical work; the L. La Caze Prize to Augustin Damiens, for the whole of his work; the Cahours Foundation to Louis Domange, for the continuation of his researches; the Paul Marguerite de la Charlonie Prize to Maurice Nicloux, for his work in chemical analysis; the Houzeau Prize to Georges Chaudron, for his studies on the reduction of the iron oxides and on their magnetic properties.

Mineralogy and Geology.—The James Hall Prize to Edouard Roch, for his work on the geology of Morocco.

Physics of the Globe.—The Victor Raulin Prize to Charles Poisson, for his work and publications on terrestrial magnetism and meteorology.

Botany.—The Desmazières Prize to René Dujarric de la Rivière, for his work entitled "Le poison des Amanites mortelles"; the Montagne Prize to Jules Lebasque for his work "Les champignons des teignes du cheval et des bovidés"; the de la Fons Mélicocq Prize to (the late) Pierre Jouane and Pierre Chouard, for their memoir "Essai de Géographie botanique sur les forêts de l'Aisne"; the de Coincy Prize to Maurice Lenoir, for his work on chromatines.

Anatomy and Zoology.—The Cuvier Prize to Jacques Pellegrin, for his ichthyological work; the Savigny Prize to Jacques Colas-Belcour, for his researches on the arthropods of North Africa; the Jean Thore Prize to Paul Vayssière, for his work on Coccideæ and the migratory Acridians.

Medicine and Surgery.—Montyon Prizes: Paul Armand-Delille, Charles Lestocquoy and René Huguenin (2,500 francs), for their work "La tuberculose pulmonaire et les maladies de l'appareil respiratoire de l'enfant et de l'adolescent"; Corneille Heymans, Jean Jacques Bouckaert and Paul Regniers (2,500 francs), for their work on the carotid sinus; Henri Lagrange (2,500 francs), for his book on ophthalmic studies. Honourable mentions (1,500 francs) to Félix Pierre Merklen, André R. Prévot and Jean Quénu. Citations to Hubert Jausion and François Pages, Carlos Lepoutre, Jean Quérangal des Essarts and Mme. Alix de Carbonnières de Saint Brice. The Barbier Prize to Georges J. Stefanopoulo, for his contribution to the study of yellow fever; the Bréant Prize between Constant Mathis (3,500 francs), for his memoir on recurrent spirochætosis, and Jacques Bailly (1,500 francs), for his work on hydrophobia; the Godard Prize to Mlle. Gilberte Pallot, for her study of microcystic ovaries; the Mège Prize to Pierre Lassablière, for his work entitled "Aliments, Régimes, Indications, Contre-indications"; the Bellion Prize to Jean Troisier and Yves Boquien, for their book on spirochætosis; the Jean Dagnan-Bouveret Prize to Auguste C. Marie and Paul Remlinger, for the whole of their work on hydrophobia.

Physiology.—Montyon Prize to Remy Collin, for his book on the hypophysis; the L. La Caze Prize to Paul Portier, for the whole of his physiological work; the Pourat Prize to Z. M. Bacq and Lucien Brouha, for their work on hormones; the Martin Damourette Prize to Edmond Benhamou, for his work on the spleen; the Philipeaux Prize to Georges Teissier for his morphological and physiological researches on the growth of insects.

Statistics.—The Montyon Prize to Pierre Jéramec (1,000 francs), for his work on statistics, and Louis Potin (1,000 francs), for his work in connexion with insurance risks.

History and Philosophy of Science.—The Binoux Prize between Paul Baud, for his book on chemical history in France, and Raoul Combes, for his history of plant biology in France.

Works of Science.—The Henri de Parville Prize to Jean Rostand (2,500 francs), for his books popularising general biology, and Pierre Sergescu (2,500 francs), for his book on the mathematical sciences.

Medals.—The Berthelot medal is awarded to Paul Bruère, Maurice Nicloux and Georges Chaudron.

Prizes Founded by the State.—The Grand Prize of the Mathematical Sciences to Emile Cotton, for the whole of his scientific work; the Bordin Prize to Pierre Frémy, for his work on the Myxophyceæ;

the Lallemand Prize to André Rochon-Duvigneaud, for his book on the eye and vision in the vertebrates: the Vaillant Prize to Henri Colin, for the whole of his work in plant physiology, the Hollevigue Prize to Léon Brillouin, for his researches and works on modern statistical mechanics, the Jean Jacques Berger Prize to Roger Boutteville, for his work in public lighting and hygiene, the Saintour Prize to Louis Dubertret, for his geological work and especially for his geological map of Syria, the Jules Mahyer Prize to Pierre Humbert, for the whole of his work in mathematical analysis, the Lonchamt Prize to Mme Marguerite Lwoff, for her memoirs on nutrition of the Trypanosomides, and André Lwoff, for his memoir on the significance of hæmoglobin for the flagellated parasites. the Wilde Prize to André Duparque, for the whole of his work on the structure and petrographical characters of coal, the Caméré Prize to Jean Aubert, for his work concerning a new system of mobile barrage, the Thorlet Prize to Paul Dorveaux, the Albert I of Monaco Prize to Jean Tilho, for his researches on the hydrography of the Lake Tchad region, the Marquet Prize to Frédéric Joliot and Mme Irène Joliot, for their discovery of temporary radioactivity

Special Foundations—The Lannelongue Foundation to Mme Gabriel Cusco, the Hélène Helbronner Fould Prize to Mme Pierre Savorgnan de Brazza

Grand Ecoles Prizes—The Laplace Prize to Jean Couture, the L. E Rivot Prize between Jean Couture, Louis Eyssautier, Michel Legrand and Yves Monneret

Grants for Scientific Researches—The Gegner Foundation to Camille Vallaux, for his oceanographic work, the Jérôme Ponti Foundation to Jean Thibaud, for his method of concentrating electrons in the magnetic field, the Hirn Foundation to Gonzague Dubar, for his work on the stratigraphy and palæontology of the Lias, especially in the Pyrenees and Morocco, the Becquerel Foundation to Yves Rocard, for his work on the kinetic theory of gases and on optics

The Loutreuil Foundation—Out of thirty five applications, the consulting committee has chosen the following

Researches on definite problems—Pierre Viala (6,000 francs), for his work on the parasite of the *Court Noué* of the vine; André Aron (2,000 francs), for his researches on the magnetic properties of thin sheets of nickel, James Basset (5,000 francs), for experimental researches on ultra-pressures, Paul Henri Fleuret (2,000 francs), for the study of ketogenesis and oxaluria Edmond Guillermet (3,000 francs), for his studies on electrolysis in solvents other than water, Mme Louis Nouvel (4,000 francs), for work in a maritime laboratory; Marcel Petit (4,000 francs), for his researches on the molars of Equideæ; Maurice Pierre (3,000 francs), for his researches on the rôle of the different physical and mechanical factors governing swallowing, vomiting and ruminating, Henri Simonnet (9,000 francs), for his researches in plant toxicology, André Wahl (3,000 francs), for the continuation of his work relating to tinctorial chemistry

Researches to be carried out in France overseas and countries under French mandate—Roger Heim (12,000 francs), as a contribution to the expenses of a voyage to Madagascar for the study of the cryptogamic flora and various diseases of trees and cultivated plants; Antoine Poidebard (7,000 francs), for his geographical studies by photography from the air in the Syrian desert

Purchase of Laboratory Material—René Dubrisay (10,000 francs), for the purchase of a Jobin and Yvon spectrograph

Publications—*Annales des sciences naturelles* (5,000 francs), for the publication of special volumes commemorating the centenary of this publication, Camille Arambourg (6,000 francs), for the publication of the scientific results of his Omo expedition; Comité de physique du globe des colonies (10,000 francs), for assisting the publication of its *Annales*, Fédération Française des Sociétés de sciences naturelles (5,000 francs), for the publication in the "Faune de France" of the memoirs of Seguy on the Acalypters and of Brolemann on the Diplopods

Grants to Libraries—Académie d'agriculture de France (5,000 francs), for assistance with its catalogue; Bibliothèque nationale et universitaire de Strasbourg (5,000 francs), for printing a catalogue of its periodicals, Ecole nationale vétérinaire de Lyon (5,000 francs), Ecole nationale vétérinaire de Toulouse (4,000 francs), Ecole Polytechnique (5,000 francs), Institut national agronomique (5,000 francs)

The Mme. Victor Noury Foundation to Raymond Poisson (3,000 francs), for his studies in protistology; Paul E. Thomas and Paul de Graeve (3,000 francs), for their work in biological chemistry, Mme. Edouard Salles (3,000 francs), for her studies on terrestrial magnetism; Edouard Lamy (2,500 francs), for the whole of his malacological work; Michel Volkonsky (2,500 francs), for his work in cytophysiology and plant physiology The Le Chatelier Foundation to René Paris, for carrying out researches on the devitrification of glass The Frément Foundation (2,500 francs) to Pierre Vernotte, for studies on the propagation of heat either by conduction or convection. The Roy-Vaucouloux Foundation to the Institut Marey.

Attacks of Birds upon Butterflies

CRITICS of the current theory of mimicry, but only so far as butterflies are concerned, claim that published records are insufficient to establish birds as the agents which may be considered mainly responsible for the production of mimetic resemblance in butterflies by preferential feeding. The following observation, communicated to me by Mr. T H E Jackson, of Kitale, Kenya Colony, is therefore of great interest to all students of natural selection. Early in the present year, at Bulumbe camp in Busia, in the eastern province of Uganda, he noted on the first night "a few wings of butterflies lying about but it was not until next morning that the truth dawned on me. I then found that the ground was literally strewn with wings There were four or five large *Spathodea nilotica* trees in the compound and swarms of butterflies were feeding on the flowers. Watching them that morning for birds I saw one swoop down on a *Papilio bromius* and take it off to a bare branch where it proceeded to beat off the wings, devouring the body only, and then returned to the tree for more. I made a list on paper of the butterflies present and only afterwards thought of

collecting the wings themselves as evidence one *Acraea* we could not find again".

The following table gives Mr. Jackson's notes, together with the results of examining the wings sent by him. The number of *specimens* was reckoned by counting the maximum number of fore wings, right or left, whichever was the greatest

Species present	Prevalence	Wings found	Estimated (minimum) number of specimens eaten (by wings sent)
Papilionidae			
Papilio dardanus	Very common	Plentiful	Males, 5
Female form *hippocoonides*	About equal numbers seen or taken	A few	Female form *hippocoonides*, 2
" " *planemoides*		None	
Papilio bromius	Very common	Plentiful	Males, 14 Females, 9 (An uneaten specimen with wings much torn also found)
Papilio nireus	A few	A few	Male, 1 Female, 1
Papilio phorcas	A few	A few	Males, 2 Female, 1 Female form *thersander*, 1
Pieridae			
Mylothris poppaea	Common	None	
Eronia thalassina	Common	Of two specimens	Males, 2
Eronia argia	A few	Of one specimen	Male, 1
Nymphalinae			
Charaxes brutus	A few *Charaxes* flying round trees and wings recovered of those mentioned, one or two of each		Male, 1
Charaxes castor			Males, 2
Charaxes etesipe			Females, 2
Charaxes tiridates			Female, 1
or *numenes*			Female, 1
Charaxes etheocles			Female, 1
Cyrestis camillus	Common, but lower down on under-sides of leaves	One or two	One
Precis westermanni	Common	A few	Male, 1
Acraeinae			
Acraea pharsalus, *Acraea viviana*, *Acraea egina*, *Acraea encedon*	Very common	Wings of three only discovered after very careful search	One male, whole except for head, and one right hind wing, of *A egina*

The following points deserve comment

(1) Several wings show such clear beak-marks that it was possible, through the kindness of Mr. N. B Kinnear of the British Museum, to compare them with imprints of the beaks of birds made by pinching soft paper between the mandibles, as was first suggested by Mr C L Collenette. The description of the birds given by Mr Jackson, whose ornithological knowledge unfortunately was not equal to his entomological, suggested a species of drongo "The birds were black and smallish without markings that one could distinguish . there were eight or nine of them." But impressions from drongos, or black flycatchers, were shorter and broader than the marks on the wings, and the nearest approach came from a species of *Lamprocolius* (glossy starling): the numbers also favour that rather than a species of drongo.

(2) Mr. Jackson noted that "the butterflies present were first Papilios and Acraeas in about equal quantities". The Papilios comprised several black and green species, and *dardanus* with cream coloured male and two forms of mimetic female The black and white *hippocoonides* resembles a species of *Amauris* (Danainae), the other, *planemoides*, has a conspicuous orange band producing a likeness to a *Planema* (*Acraeinae*). The males and black and white female were eaten, the other female was not "Both forms appeared to be equally common , we took four of the former and three of the latter, and saw one more of the latter. No models for either form were observed." The latter remark, of course, simply implies that the models were not feeding on the trees: *Amauris* is exceedingly common.

(3) Evidence that Acraeas are relatively distasteful is supplied by the small numbers of wings of these very common insects found on the ground One specimen "which is perfect except for the head was actually dropped at my feet under the tree while I was collecting the wings". It must be said, however, that the specimens sent comprised a *Papilio bromius*, the body of which was undamaged although the wings were torn *Acraea egina* is extremely abundant, black and scarlet , the less common *pharsalus* is of the same colour , *encedon* and *viviana* are yellowish or brownish , they have all the characters demanded of species relying upon brilliant colours to advertise distasteful qualities It is highly suggestive that the female *dardanus* which has an acraeine appearance was untouched

(4) The large bodied *Charaxes* (allied to our 'Purple Emperor' in habits) were evidently in demand, for wings of all the species seen were picked up This confirms the evidence of Mr C F M Swynnerton[1]

(5) Some of the 'Whites' (Pieridae) were common, but apparently not greatly in favour The two *Eronia* are white or greenish white , the *Mylothris* has a brilliant orange patch at the bases of the wings which is generally held to be an example of 'warning colour' , like *Acraea*, *Mylothris* is typically aposematic in habit, is mimicked by other butterflies, and is known by experimental evidence to be relatively distasteful It will be noted that *M poppaea*, 'common', was not attacked, while *Eronia* was.

(6) This most interesting and valuable observation does not support the statement so strongly emphasised by Mr. W L McAtee[2] that "predation takes place much the same as if there were no such thing as protective adaptations" and that "there is utilization of animals of practically every kind for food approximately in proportion to their numbers".

(7) Regarding published records, the difficulty has been in the past that many experienced naturalists have not thought it worth while to record the details of what they consider to be a "commonplace occurrence"[3] The Hope Department, Oxford University Museum, has put together a body of evidence in the form of beak-marks upon the wings, which are constantly being discovered now that their appearance is recognised During recent years, descriptions of many such have been published in the *Proceedings of the Royal Entomological Society of London*

(8) It has been said that migrations of butterflies should afford evidence, if butterflies are devoured by birds to an appreciable extent. Observations on this have been published, but attention may be directed here to notes in a recent book of travel[4]

Rediffusion and Teleprogramme Systems in Broadcasting

'REDIFFUSION' is a method of distributing a broadcast programme over an independent line network to a number of subscribers. 'Teleprogramme' is the method which enables a telephone subscriber, by means of a small amount of additional apparatus, to receive the ordinary radio broadcast programmes over his telephone network. The object of both systems is the same, namely, to reproduce the broadcast programme in the subscriber's home with the maximum fidelity, but the means employed are quite different.

A good paper by Mr. A. R. A. Rendall and Mr. S. Van Vierlo discusses the two methods in *Electrical Communication* of October. Both methods are in use in various parts of the world. In rediffusion, the programme is usually received by radio; but it is better, when possible, to get direct reception from a studio. An amplifier station delivers the oscillations at such a level that all the subscriber needs to do is to bridge his loud speaker across the terminals. The sounds are then heard at the proper loudness, no adjustment being necessary. The choice of programmes is restricted, as although alternative programmes are easily provided, they add appreciably to the cost of the service. Recently designed systems offer a choice of four programmes. Considering this is all that is generally heard free from interference at an ordinary receiving set, this is satisfactory.

The success of the system depends a great deal on the position chosen for the amplifier station and the cables used for connecting it with the consumers. It should be near the centre of gravity of the load, and shielded cables should be used. In these undertakings, the maintenance of a high and uniform standard in the quality of the reception is essential if they are to compete successfully with receiving sets, the prices of which are being continually reduced. A partial failure or even periods of poor quality would seriously affect their prospects of success.

In a teleprogramme system, the radio broadcast is received on the subscriber's premises over his ordinary telephone network. This additional use of his telephone is sometimes a boon when it is not much used during the day and rarely in the evening. It is obviously a serious inconvenience to have the programme interrupted by a telephone call. Hence for subscribers with a high calling rate, an additional telephone cable is necessary to convey the programmes, and this adds to the expense. In most cases the subscriber has a choice between several programmes. By controlling a step-by-step selector at the telephone exchange, he is able to get the programme he wants. In this system it is necessary to limit the service to the normal speech level, and so an amplifier as well as a loud speaker has to be employed. In the rediffusion system this is not necessary as the transmission level is much higher. As the mere act of taking his receiver off the switch hook disconnects his amplifier, the subscriber can always use his telephone by interrupting the programme.

When considering the apparatus necessary for the supply of a group of 500 subscribers, it is customary to assume that not more than 60 per cent of them will be connected to a particular programme at the same time. In this case the amplifiers are usually rated for a power varying from 2 to 40 watts.

University and Educational Intelligence

CAMBRIDGE.—Mr. W. V. D. Hodge, University lecturer in mathematics, has been elected into a fellowship and appointed lecturer and director of mathematical studies at Pembroke College. Mr. Hodge was educated at George Watson's College, Edinburgh, the University of Edinburgh and St. John's College, Cambridge. He obtained a first class in Part 2 of the Mathematical Tripos in 1925 and was awarded a Smith's Prize in 1927. He also studied at Princeton University while holding a Senior 1851 Exhibition in 1926-31. He was on the staff of the University of Bristol and held a fellowship at St. John's College from 1930 until 1933.

EDINBURGH.—The Cameron Prize for 1935 has been awarded to Prof. Julius Wagner Jauregg, emeritus professor of psychiatry and neuropathology in the University of Vienna, in recognition of his discoveries regarding the malarial treatment of general paralysis.

LONDON.—The following titles have been conferred in respect of posts held at schools of the University: professor of chemistry, Dr. J. W. Cook, the Cancer Hospital (Free); reader in organic chemistry, Dr. G. A. R. Kon, Imperial College—Royal College of Science.

The William Julius Mickle fellowship for 1935 has been awarded to Dr. Solly Zuckerman.

The Carpenter Medal for 1934 has been awarded to Dr. R. J. Lythgoe.

MANCHESTER.—Dr. A. H. Gibson, Beyer professor of engineering, has been appointed a pro-vice-chancellor, for a period of two years as from January 23, 1935, on the resignation of Prof. Lapworth.

Dr. F. P. Burt, reader in stoichio-chemistry, has been elected dean of the Faculty of Science for two years from January 1935.

Dr. W. N. Bailey, senior lecturer in mathematics, has been appointed Richardson lecturer in pure mathematics.

The Research and Standardisation Committee of the Institution of Automobile Engineers has presented to the Engineering Department an experimental petrol engine, and Mr. Charles Day, of Messrs. Mirrlees, Bickerton and Day, Limited, has loaned a Ricardo Diesel engine complete with all testing equipment.

THE American adult educational enterprise known as "The University of the Air" is now entering upon its third year. Prof. John Dewey, addressing an audience of sixteen hundred on December 8 at New York City Hall on "Radio's Influence on the Mind", claimed for broadcasting that it is the most powerful instrument of social education the world has ever seen and one urgently needed to redress the balance between the modern means of exchange of physical things and those of knowledge and ideas. One of the most crucial problems of to-day is how to ensure the employment of this instrument for the social public interest, in preference to its use for propaganda designed to distort facts and mislead the public mind. The 1935 programme embraces talks on: education for a new social order, economic planning, psycho-analysis and studies in a museum.

THAT biology should be taught in all schools to all pupils is one of the conclusions of the argument developed by Dr C J Bond, Fernshaw, Springfield, Road, Leicester, in an address delivered to Section L at the Aberdeen meeting of the British Association last year The address is now obtainable in pamphlet form Young people suffer to-day from no sound biological foundation having been laid during school life for, at any rate, three departments of life in civilised societies (1) sex, marriage and parenthood, (2) citizenship, (3) vocation For (1) the foundation should include instruction in the general principles of genetics, including human heredity, with examples drawn from plant and animal life, and wise advice and guidance should be made available during school life and to young persons of both sexes who wish to marry As regards citizenship, our present system of national education is marred by a lack of continuity and completeness answerable for the existence of a false conception in many minds of the real nature of individual liberty and of conflict of individual, social and racial interests Vocational guidance is obviously more important for the welfare of the young citizen and prevention of waste of human capacity than examination of scholastic acquirements It can only be given by skilled experts able to assess natural aptitudes and equipped with technical knowledge of the conditions and requirements of the diverse occupations open to 'school leavers', and this combination of psychological and technical knowledge must be acquired during and after the period spent in teacher training colleges by teachers specially interested in industrial life and vocational guidance. The address touches also on the steadily increasing ratio of old to young in the population, on biology and culture, on education in the right use of leisure and the limits of what can be achieved by education.

Science News a Century Ago

The Linnean Society

On February 3, 1835, at a meeting of the Linnean Society at which A B Lambert was in the chair, B H Hodgson, Dr Kidd of Oxford and R. Garner, whose paper "On the Nervous Structure of Molluscous Animals" had lately been read, were elected fellows of the Society. The secretary read a paper by Mr Bentham of the Horticultural Society "On the Various Species of the Genus *Lotus*, and the Allied Genera". The chairman exhibited the flowers and leaves of *Dracæna terminalis*, a plant from the islands of the Pacific successfully cultivated at his own residence in Wiltshire The flowers were used by the natives of the islands, he said, to flavour a liquid like beer, and the fibres of the long leaves served as threads. Profs Bartolomi, Fries, Harlan, Harrold, Lichtenstein and Reinwardt, with Baron Delessert, were nominated to fill the vacancies in the list of foreign members

Meteorology at the Cape of Good Hope

Writing from Edinburgh on February 5, 1835, to Sir John Herschel at the Cape, J. D Forbes said . "I had a letter from Whewell the other day, communicating your obliging message to me about your very interesting meteorological results. . . The annual variation of mean pressure and also of hourly oscillation you mention is noticed by Humbolt in equatorial climates. Is the barometer highest in summer or winter ? I fear we are likely to find little analogous to your observations at the Cape in the Mediterranean The oscillation is undoubtedly greater and I do not think the barometer is highest in bad weather The variable pressure in different latitudes is a very important and to me, till lately, an unexpected fact I hope that you will be able to bring your barometer safely home again, and so determine the height of your observatory I hope you have your actinometer with you , here it has a sinecure, there being no sun worth measuring "

Henry's Electrical Experiments

On February 7, 1835, Prof A D. Bache wrote to the Committee of Publications of the Franklin Institute saying that "The American Philosophical Society, at their last stated meeting, authorised the following abstract of a verbal communication made to the Society by Professor Henry on the sixteenth of January last A memoir on this subject has been since submitted to the Society containing an extension of the subject, the primary fact in relation to which was observed by Professor Henry as early as 1832, and announced by him in the American Journal of Science Mr Faraday having recently entered upon a similar train of observations, the immediate publication of the accompanying is important, that the prior claims of our fellow countryman may not be overlooked" Bache's letter was followed by an abstract from the report of the meeting of the American Philosophical Society which contained details of Henry's experiments with electric currents

Death of Baron Dupuytren

On February 8, 1835, Baron Guillaume Dupuytren, the foremost surgeon in France, died in Paris Born in humble circumstances at Pierre Buffière in Limousin on October 6, 1777, it is said that he was stolen when three by a lady of rank, but was afterwards recovered by his parents Both in appearance and by his conversation he attracted the attention of people, and at the age of twelve years through the action of an army officer he was sent to the Collège de la Marche in Paris, and his youth was thus passed amidst the turmoil of the French Revolution Subsisting on the most meagre of allowances, he was, however, able to study chemistry and anatomy and at the age of seventeen years, in 1794, obtained a post in the new School of Medicine founded under the direction of Fourcroy. From then his progress was unchecked In 1803 he was made an assistant surgeon at the Hôtel-Dieu, in 1811 succeeded Sabatier in the professorship of operative surgery and in 1815 he was given the chair of clinical surgery, which he held until his death. He was also surgeon to Louis XVIII "Haughty, austere, and brooking no rivals," says Seelig, "he trod through life always upwards, charming by his very disdain and constantly introducing technical innovations that have stood the test of time. By a queer twist of fate, one of the least significant of his accomplishments, a description of contracted palmar fascia, is the one to which his name has clung". The perseverance he had shown amid the difficulties of his early years was not more notable than the assiduity with which he always carried out his duties and the iron resolution which astonished all who came in contact with him He was buried in the Père Lachaise cemetery, and a part of his large fortune was used for the founding of the Musée Dupuytren near the École de Médicine, Paris.

Societies and Academies

LONDON

Royal Society, January 24. M BORN and L INFELD On the quantisation of the new field equations (1) The new field theory uses the primary field vectors **E**, **B** and derives secondary field vectors **D**, **H** by differentiating the Lagrangian L (**E**, **B**) with respect to **E**, **B**. If one gives up the invariant form (that is, the four dimensional tensor notation), one can introduce other pairs of primary variables, in each case there exists an action function, one of which is the energy density Using this representation it is possible to formulate the quantum laws of the field The field equations can be written without any space or time derivatives, only by means of commutators connecting the field vectors with the total energy and the total momentum They formulate a coherent unitarian quantum theory of matter and field (2) The commutation rules for the field components are given in a new form which makes no use of δ-functions The behaviour of an electrodynamical system as a whole is described by a set of integral quantities total energy, total momentum, centre of energy, total angular momentum These quantities satisfy commutation rules which can be derived from those for the field components The chief result is that the co ordinates of the centre and the components of the total momentum are connected by the same commutation laws as in quantum mechanics, and that the components of the momentum commute, but the co-ordinates of the centre do not commute H BETHE and R PEIERLS The scattering of neutrons by protons The result is practically independent of the special law of force assumed between neutron and proton, it depends only upon the known binding energy of the diplon. The cross-section obtained is about 50 per cent larger than the rather uncertain experimental value. The scattering is almost isotropic (in the relative co-ordinate system) for neutron energies up to about 40 million volts

EDINBURGH

Royal Society, January 7. ESTHER LOWE. Anatomy of a marine copepod, *Calanus finmarchicus*, Gunner. A muscular mechanism in the heart wall opens the aortic valve and closes the ostia during systole Circulation is assisted by rhythmical movements of the pericardial floor, involving alternate contraction of two sets of muscles A paired series of canals returns blood to the pericardium A pair of giant fibres in the nerve cord, arising by a chiasma in the brain, give off branches supplying, alternately, the dorsal longitudinal trunk muscles, which determine direction, and the flexors of the swimming feet, which accomplish the darting movement The system, evidently, constitutes the effector portion of an escape reflex. GERARD DE GEER: Dating of late-glacial clay varves in Scotland. A measurement by Dr. J. B Simpson of varved clay exposed by the River Earn near Dunning, Perthshire, has been correlated with a series from Lyngby, near Copenhagen. According to this correlation, the Dunning section corresponds to an early stage in the goti-glacial sub-epoch of the Scandinavian ice-retreat, dating from about 13,000 years ago J. WALTON: The fossil hollow trees of Arran and their branches, *Lepidophloios Wünschianus*, Carruthers In 1865, Edward A. Wünsch, of Glasgow, made the interesting discovery that there were fossil trees in position of growth in the Lower Carboniferous volcanic ash beds on the north-east coast of Arran in the Clyde. The new methods which are available for getting sections of fossil plants are such that there is almost no limit to the size of block of material from which a section may be prepared The trees had partly decayed before preservation and the hollow trunks contain fragments of many different kinds of plants (for example, *Bothrodendron*, *Protocalamites*, *Lyginorachis*), all very well preserved structurally The trees themselves prove to belong to the genus *Lepidophloios*, a near ally of the better-known Carboniferous genus *Lepidodendron*. Only the bases of the trunks are preserved In four examples the central core of wood is found, and from its structure something of the mode of growth of the original tree may be deduced. It is also evident that, like the nearest living representatives of this extinct genus, *Selaginella* and *Isoetes*, these gigantic trees developed from spores By careful comparison of histological features, it has been possible to identify various sized branches and twigs found in the same beds as parts of the plant which possessed the large trunks IAN SANDEMAN The mathematical representation of the energy levels of the secondary spectrum of hydrogen (2). An analysis of the two states, $1s2s^3\Sigma$ and $1s2p^1\Sigma$, of H_2 is carried out on the basis of J L. Dunham's solution of the wave-mechanics equation for the diatomic molecule The consistency of the results indicates very little evidence of l uncoupling for these states Potential functions are obtained which indicate that the potential function of Morse is not applicable to the two states

PARIS

Academy of Sciences, December 26 (*C R*, **199**, 1537–1694) The president announced the death of Willem de Sitter, *Correspondant* for the Section of Astronomy JEAN CHARCOT Notice on the works of M de Gerlache A LACROIX. The discovery of tectites on the Ivory Coast Description and analyses of three specimens of tectites from West Africa H DESLANDRES: A simple and general relation of the molecular spectrum to the electrons and rings of electrons of the constituent atoms JULIEN COSTANTIN, JOSEPH BOUGET and JOSEPH MAGROU: New experiments on the germination of the seeds of the potato in the mountains (1934) Comparison of the results of the culture experiments in 1933 and 1934. HYACINTHE VINCENT: Streptococcæmia and suppurating meningitis with streptococci The action of antistreptococcus serum in these infectious states. The author considers that the value of his serum treatment is best tested on the most serious forms of streptococcal infection, septicæmia and suppurating meningo-cephalitis. Of 218 such cases, 180 were cured CHARLES NICOLLE and PAUL GIROUD The observation of the Tunisian epidemics of historic and murin typhus and the study of their virus, showing that these two diseases are separate CHARLES CAMICHEL and LÉOPOLD ESCANDE. Royal National Academy of the Lincei: Communications received during the vacation of 1934. G. A. Crocco: The conception of 'focus' in the stability of aeroplanes. A. Russo: Elimination of nuclear substance and adhesion of the gametes in a ciliate, in relation to the agglutination in the fertilisation of Metazoa. S. Sarantopoulos: A theorem concerning the method by recurrence (complete induction). G. Belardinelli: A class of analytic functionals (1). N. Moisseiev: The curves defined by a system of differential equations of the second order (2). Certain properties of the trajectories in Hill's problem of three bodies. Previous study of dynamic problems with two degrees of freedom revealed the existence, on the plane of motion, of a geometric locus of the points in which occurs contact of the trajectories with a given family of curves, $f(x, y) =$ constant. This contact was not lower than the second order. Such a curve is now applied to the study of the properties of the trajectories in Hill's problem. (3) Concerning a method of studying the integral curves in the system of three differential equations of the second order. G. L. Andrissi: Measurements of double stars. Measurements made on a number of double stars from Burnham's "General Catalogue of Double Stars" (1906) by means of the 7-inch Cauchoix-Cavignato equatorial at the Campidoglio Observatory are recorded. A. G. Barbieri: Compounds intermediate to ferrocyanides and ferro ammines. When treated with potassium cyanide, ferro-dipyridyl and ferro-phenanthroline compounds of the type $[FeB_3]X_2$ ($B = \alpha\alpha^1$-dipyridyl or *o*-phenanthroline) yield ferrocyanide, with intermediate formation of compounds of the structure $\left[Fe{}^{B_2}_{(CN)_2}\right]$ and $\left[Fe{}^{B_2}_{(CN)_4}\right]K_2$, containing either two or three molecules of water of crystallisation. G. Scagliarini and M. Ragno: Influence of temperature on the formation of additive compounds. In the cold, cobalt chloride and bromide react with pyridine, giving the compounds $CoCl_2, 4C_5H_5N$ and $CoBr_2, 4C_5H_5N$. If, however, the solutions are kept for some hours at 70°–80°, the salts crystallising out contain only two molecules of pyridine per molecule of the cobalt salt. Other similar cases are recorded. Carmela Manunta: Origin of the uric acid in the hibernating eggs of the silkworm. Experimental data confirm the hypothesis that this uric acid is derived largely, not from embryonal metabolism, but from the maternal blood.

Vienna

Academy of Sciences, November 29. Richilde Wagner: Admittance of radium emanation into the human body through the skin. The skin is slightly permeable to the emanation but this is, as a rule, not the chief means of access of the emanation to the organism from baths. Max Pestemer and Bruno Litschauer: Ultra-violet absorption of mustard oil and of the thiocyanate group. This absorption is determined mainly by the sulphur atom of the thiocyanate and isothiocyanate group. Max Pestemer and Gerhard Schmidt: Ultra-violet absorption of binary liquid mixtures (6): the system ethyl thiocyanate – hexane. The curves representing the extinction coefficients of these mixtures are positive in comparison with those calculated additively. Paula Bernstein: Ultra-violet absorption of the system aniline – *m*-cresol in ethanol. In 0·01 and 0·1 molar solutions, the extinctions of these mixtures are virtually additive, although an equi-molecular compound is formed; such compound apparently decomposes at the above dilutions. Max Pestemer and Bruno Litschauer: Ultra-violet absorption of the system acetone – benzene. In agreement with the results obtained for the system acetone – hexane, the extinction of the acetone is positive in comparison with the additive values for the mixtures. That of the benzene is, however, negative, probably owing to an inductive action of the polar acetone.

Forthcoming Events

The Planting of Hardwood Trees

RECENT correspondence in the Press, to which Mr. Alexander Howard refers in a letter on p 231 of this issue, has directed attention to the alarming rate at which hardwood trees, whether isolated or in hedgerows, woodlands or otherwise, are being felled in many parts of Britain without any attempt at replanting Various reasons for this state of affairs might be given, including high taxation, which has forced landowners to realise every possible tree in an endeavour to retain possession of their property, the general depression, the break-up of estates, the high level of wages, the remoteness of prospective yields and uncertainty as to the future, which prevent landowners from sinking capital in long-term investments such as plantations On the other hand, it should be mentioned that recent legislation provides a large measure of relief in regard to taxation and death duties , among other things, for purposes of probate the value of woodlands is excluded from the total value of an estate, and a landowner therefore stands to benefit his estate by storing up capital in the form of growing timber.

It will be convenient if we approach this question from two points of view, the æsthetic or sentimental on one hand and the economic or utilitarian on the other These are not necessarily antagonistic Opinions on the æsthetic value of different classes of trees are governed so much by personal taste or sentiment that agreement on the subject can scarcely be expected But misdirected sentiment has been responsible for some confusion of ideas. Some writers advocate the wider use of our 'native hardwoods', but include among them various introduced species, such as the 'common' elm, the sycamore, the lime, the walnut and others At the same time, they have condemned the use of conifers, partly for æsthetic reasons and partly because all our coniferous timber trees except the Scots pine are exotics. This attitude is scarcely reasonable, for among the conifers are to be found some of the most beautiful and interesting trees in the world. Let it be admitted, therefore, that conifers, when used with discretion, have their æsthetic value as well as hardwoods But when we find, as we now do, that the hardwood trees which have been the glory of English scenery in the past are being extensively felled, and if replaced at all are being replaced mainly by conifers, it is time to call a halt. Here we touch the economic and utilitarian side of the question

So far as requirements in bulk are concerned, coniferous timbers (softwoods) are of much more importance than hardwoods They constitute about eighty per cent of the world's consumption of sawn timber, and are used in large quantities for pitprops, telegraph and other poles, paper-pulp and other purposes Owing to the depletion of the world's timber resources, a serious shortage of softwoods within a measurable period of time is predicted, though hardwoods in general will not be affected to anything like the same extent It is partly for this reason that in the programme of State afforestation proposed by the Acland Committee of 1916–17, and now being carried out by the Forestry Commission, the area to be afforested with conifers was estimated at 1,770,000 acres and that required for hardwoods at only 100,000 acres, or about 5 3 per cent of the total This policy has been modified recently in favour of an increased use of hardwoods for afforestation in localities suitable for them, and actually more than six per cent of the total area afforested to date has been planted with hardwoods The planting of hardwoods, however, is restricted by the fact that the price to be paid by the Commissioners for land is fixed at a comparatively low figure This means that much of the land acquired is too poor for the cultivation of the more valuable hardwoods, and is fit only for the less exacting conifers. Nevertheless, in areas planted with conifers steps are being taken, on æsthetic as well as on sylvicultural and protective grounds, to introduce broad-leaved trees along the sides of roads, and even within the plantations.

That the private landowner should replace the previously existing hardwood crops by coniferous plantations is not altogether surprising The latter may possibly yield returns within the lifetime of himself or his heir, but there is small hope of this in the case of the former, if we exclude such short-rotation crops as chestnut coppice and the like Leaving æsthetic and sentimental considerations out of account, therefore, are there any economic or technical reasons why hardwoods should continue to hold an important place in British forestry? The answer to this question is a decided affirmative. Although the total consumption is considerably less in the case of hardwoods than of softwoods, there are many special purposes for which hardwoods, and definite species of hardwoods, are alone suitable , and it is important that future supplies of such woods should be ensured. Again, extensive afforestation with introduced conifers is attended with considerable risk from insect pests and fungus diseases, particularly in a country like England, the natural forest vegetation of which consists predominantly of broad-leaved trees France is now learning this to her cost in the Seine valley, where forests of introduced Scots pine, created on a large scale early last century, are being decimated by fungus diseases A generous mixture of hardwoods in coniferous crops is one of the best safeguards against such a calamity, and it has the further advantage of reducing the risks from fire and storms as well as of maintaining the fertility of the soil, and with it the health and vigour of the crop To summarise the position, although there are strong economic reasons for the extensive use of conifers for afforestation, there are equally strong reasons, from several points of view, for paying special attention to the cultivation of hardwood trees

When we come to consider the question of preventing the destruction of existing woodlands and trees, preserving the beauty of the countryside, and ensuring future supplies of hardwood timber, we are faced with problems of a somewhat complicated nature State afforestation may be expected to continue, possibly on a more extended scale, and it is hoped that hardwoods will receive due attention A great deal more might be done by corporations and municipalities to acquire, and even create, woodland areas within easy reach of towns , the numerous town forests in France, Germany, Austria and other Continental countries, which are so great a boon to the town-dwellers, serve as an example of what might be done in Britain It is when we consider the question of private estates that the problem presents special difficulties In some Continental countries, stringent laws exist for ensuring the proper management of private forests and the regeneration of all areas felled. There is much to be said for introducing legislation designed to ensure the regeneration of felled areas, and to improve the admittedly faulty management of so many private woodlands in Britain.

On the Continent, legislation of the kind indicated applies generally to properties with a stated minimum woodland area, and its object is primarily economic. It would not cover the case of individual or hedgerow trees, or that of the numerous small copses, belts of trees, and woodland dells which are such a feature of the English countryside. The Irish Free State, by the Forestry Act of 1928, is making serious efforts to restrict the felling of trees on

private property. In Great Britain similar restrictions, however well-meaning, might prove difficult and costly to apply in practice; better results would probably be achieved, at less cost, by a policy which would give landowners more encouragement to maintain the beauty of their estates as their forbears did Something might be done by means of State aid to bodies such as the National Trust, for the acquisition of small woodland areas or park lands to be preserved primarily for æsthetic reasons Last, but not least, there is great need for educating the British public to respect trees and woodlands, which suffer from acts of vandalism unheard of in those European countries in which the 'tree sense' or 'forest conscience' is more fully developed with the help of schools, the rising generation, at any rate, might be brought up to realise that trees and woods are a heritage which should be valued and respected

Reviews

The Concept of Time in Physics

The Serial Universe By J W Dunne. Pp 242. (London: Faber and Faber, Ltd, 1934.) 10s 6d net

IN 1927, Mr Dunne published a book recording dream experiences which seemed to indicate prevision of future events Being a thorough Copernican, he scorned the idea of personal peculiarity and began to examine the concept of time His conclusions were so strange that stronger observational evidence was generally demanded; yet it was clear even then that the theory was grounded on the general nature of thought rather than the particular data of experience The issue is now cleared In his new book, Mr Dunne applies his theory to the facts of modern physics instead of to dreams Those facts are numerous and authentic enough · we can no longer evade the challenge by demanding further evidence.

Mr. Dunne's presentation of his case deserves the highest praise The book is a model of clear thought and expression, and the style excites interest to the point of fascination without sacrifice of critical attention. A mathematical physicist might have expressed a few points differently, but that is immaterial Whatever verdict awaits the ideas, their cause could scarcely have found a better advocate.

The theory starts from the idea of a *regression*, that is, a series of terms of which each, after the first, demands the next, and which therefore extends to infinity. An artist paints a picture of the universe. But he is a part of the universe, so the picture must include a picture of himself painting the same picture—which, being the same picture, must itself include him; and so on *ad infinitum*. This is a type of all regressions. The first term (the universe) alone does not require the remainder, but when the artist in the second term enters the picture, there is no escape; we are doomed to follow the succession of artists and pictures to the bitter endlessness.

Consider, now, an objective world, A, described from the indications of independent instruments, B The instruments observe *now*, but we define the world as extended in time, and from memory and calculation represent it as a static four-dimensional thing, along the time dimension of which our instruments move from past to future The instruments, however, are not inherently independent of A, being so regarded only when they are observing it a wider view of A shows it as including B But that puts the artist into the picture The sequel is inevitable.

This process is linked with the notion of time. The world, A, extends through time, T_1, along which the instrument moves, making contact only at the 'now' But such a movement requires another time, T_2. the first—a static dimension through which A extends—cannot give meaning to the motion of B along itself When we retreat a stage and contemplate, as a single system, A with its T_1 and B moving in T_2 to observe A, a third 'time' becomes necessary Thus we regress—indefinitely

At each step the abandoned time becomes a new dimension of space—of a continuum, that is, which has as many dimensions (including the three dimensions of 'ordinary' space) as there are possibilities of independent continuous variation of the system located in it. Thus we normally imagine a three-dimensional space world changing in time. When we consider its history, we petrify its eternal progress along T_1 into an A having what is equivalent to infinite space extension in that dimension, and transfer the dynamic element of time to T_2 When we withdraw to watch B observing A, T_2 in turn is fixed, its spirit flying out along T_3 At the next step, the Gorgon's head is shown to T_3, and the vital spark escapes along T_4. Whenever T_n is time, there are $n+2$ dimensions of space—the familiar three plus the $n-1$ quiescent eternities.

We can picture the process as a mad pursuit

of eternity or a relentless tracking-down of change; in either case the effort is Sisyphean. No sooner do we grasp eternity than it is transformed to infinity: we cannot arrest the passage of time in one direction without releasing it in another. The task, however, is not forced on us. We can stop at any stage, provided we stop at the corresponding stage of the physical regress. Thus, if we want only the ordinary three dimensions of space, we must not consider the world as extended in T_1, but merely as existing from moment to moment. The contemplation of world-history commits us to a fourth space dimension and a time, T_2.

The poetry of all this is irresistible, but we are concerned with the truth. Physics explores the world by arbitrarily selecting parts as instruments and giving them independent status. It is thereby committed to a regressive time concept which it has not employed. Anomalies are therefore found: we are involved in 'imaginary' time and indeterminacy. Only by accepting the fact of regression can these anomalies be removed.

Before proceeding to the removal we must examine the general idea, and here caution is necessary. Mr. Dunne's theory—belonging, as we have said, to the world of thought—appeals to a wide public—to the philosopher, the physicist, the psychologist, the humanist and the man in the street. Our point of view is that of the man of science, and we have no intention of leaving it, but we must state what it is.

Science is concerned with pure thought only in the correlation of experience. Our minds, however, can form far more concepts than experience needs. From the scientific point of view, these additional concepts are meaningless; they serve only for intellectual exercise.

History shows that no human power has been more diligently employed than that of asking meaningless questions. We do not attribute this to irony in Nature; it appears to be a by-product of our self-chosen instrument of language. "Who hath given man speech, and who hath set therein a snare?" asked Swinburne. The realm of significance is a mere patch in a boundless waste of grammatical possibility, and no scientific duty is more urgent than that of keeping within its limits.

Many philosophers will not assent to this. They (the 'nominalists' we may call them for identification, without historical or other implications) attach significance to pure thought unrelated to experience. We need not argue the matter here, for our purpose is simply to point out that Mr. Dunne sits above the controversy, calmly telling the disputants the conditions they must respectively observe. The nominalist must accept the whole infinite regression: the man of science, it seems to us, is committed only to the second term—and, with a different history, might have stopped at the first. Let us illustrate this by the example of time.

The regression of time is interwoven with the method of describing the world by selecting parts of it as instruments. The obvious conclusion is that the world should be described otherwise. Science does not in principle depend on experiments: we could merely watch things happen and rationalise the results. For speed, of course, we adopt the experimental method, but it is a *method*, not an essential quality, and we must not attribute to the universe characteristics which belong only to our mode of describing it.

This, however, is no reply to Mr. Dunne. To propose now to renounce the division of the world into instruments and systems observed would be quixotic. The division belongs not only to our experimental procedure but even to our definitions. Take, for example, such a fundamental notion as the strength of an electrostatic field. This is defined in terms of the force it exerts on a unit pole. But the pole changes the field, and the field changes the pole-strength. Instead of expressing the observed behaviour of the whole system, we describe an exploration of a hypothetical field by a hypothetical unchanged pole. The whole of physics is formed of such inventions.

The only practicable course is to adapt our concepts to this procedure. The structure of physics is so massive that it is much simpler to stand on our heads than to invert it, and this Mr. Dunne teaches us to do. Only the nominalist, however, must make the complete overturn. The physicist has merely to cock his head sideways, for one additional element of the regression will correct his imperfect start. Mr. Dunne is unanswerable when he claims that physics has effectively created two notions of time, but we cannot follow him in giving physical significance to others. Physics does not employ a second instrument to watch the first observing the world. In retreating to contemplate such a process, therefore, we step outside the patch of significance into the waste of purely verbal relations.

Using two time dimensions, Mr. Dunne gives an attractive derivation of the world of special relativity. Here time has become space; that is, it has shed its 'becoming' character and assumed infinite extension. But our clock measures becoming; we cannot put it when we like in time as we can put a metre-stick where we like in space—it ticks only when it is. Before using it as a scale for petrified time, therefore, we must multiply its readings first by i to rotate them through 90° to the T_1 axis; and secondly by a factor c to convert the unit of vital time into

that of dead time, or space This factor Mr. Dunne calls "the velocity of the now"; that is, the rate at which the instrument, which touches the world A only at the now, travels along the T_1 dimension of that world. Distance along T_1 in space units is thus icT_1, or simply icT, since T_2 is measured as time.

This sounds fantastic, but it is rigidly logical "The velocity of the now" is no more fanciful than the familiar idea that for a man travelling with light, time stands still; he is a travelling 'now' The significance of this natural 'velocity', dT_1/dT_2, however, is obscured when c is regarded as the velocity of light, for that is dS/dT also, but it becomes extremely suggestive when we consider the ratio of the electromagnetic and electrostatic units That ratio also is c, and issues from experiments in which it cannot be interpreted as dS/dT without introducing *ad hoc* conceptions We get a new view of the matter when we consider that in the two systems of units we are implicitly defining time in its moving and static aspects

Scarcely less illuminating is Mr Dunne's discussion of the principle of uncertainty He shows that this arises from the division of the world into instruments and observed systems, and that we can make the uncertainty regress with the instruments, leaving a determinate world behind The fact that this principle had nothing to do with Nature we had discerned before, but Mr. Dunne's treatment puts it in the clearest possible light.

We are less impressed by Mr Dunne's interpretation of the quantum of action, which perhaps we have not fully understood, nor do we take kindly to his more general philosophy. Taking force, space and time as elementary indefinables, he works out a scheme of dimensions for each term of his regressive observer, and gives a refutation of subjective idealism in which we feel he has been anticipated by Samuel Johnson His aim is to reconcile physics and psychology, and the effort is very ingenious We doubt, however, if a union of the most with the least developed of sciences is yet possible, and we think that in attempting it Mr Dunne is sacrificing the substance of his idea for the shadow. If force is elementary the passage to general relativity is closed, for that does not recognise force. There is fascination, at least, in describing the physical world in purely temporal terms, putting icT for space and $(ic)^2 T$ for mass, in relativity fashion; and Mr. Dunne's picture of ic as an operator which rotates one dimension of time into the next presents an imaginative aspect of the process which we feel is badly exchanged for a questionable psychological interpretation.

We are unable also to accept Mr. Dunne's assurance of immortality It seems to us that on a priori grounds this question can be answered only by experience, and when pure reason offers an answer we can only look for the fallacy Mr. Dunne argues that the destruction of observer 1, moving along T_1, cannot affect observer 2 moving along T_2, and therefore, since there is no reason why observer 2 should die, he goes on observing In familiar language, bodily death does not prove cessation of consciousness We agree, but neither does it prove continuance of consciousness There is no reason, apart from experience, why observer 1 should cease in T_1, we simply find that he does Similarly it seems to us that observer 2 might (or might not) cease in T_2, we must wait and see.

Mr Dunne's book contains so much of real value, however, that only with great reluctance do we record what we believe to be its weaknesses That a man untrained in theoretical physics should have penetrated the jungle of relativity and quantum theory and reached the central clearing is an event of such magnitude as to make ridiculous any preoccupation with the scratches received on the way Mr Dunne's achievement is a great one, and we hope it will receive the recognition it deserves HERBERT DINGLE.

Sex and Culture

Sex and Culture By Dr J D Unwin Pp. xxiv + 676 (London Oxford University Press, 1934) 36s net.

THE principal thesis of this highly elaborate investigation is that there is a causal relationship between sexual opportunity and cultural condition Sexual opportunity is measured by the kind and amount of regulation that societies employ for controlling or checking the sex impulses before and after marriage Cultural condition is used in a very narrow sense to stand for the manner in which a people conceives of the power or powers in the universe, as judged by the outwardly observable steps that are taken to maintain right relations with it or them.

Dr Unwin distinguishes three types of cultural condition the deistic, which applies to peoples who carry out their rites in temples, through the agency of priests, the manistic, which refers to peoples who pay post-funeral attention to the dead, and the zoistic, or peoples who do neither of these things. The transition from the zoistic to the deistic cultural condition indicates, according to Dr Unwin, a growth of thought, reflection and energy Sexual opportunity is determined principally by asking whether or not a people condemns pre-nuptial unchastity. Dr. Unwin claims that an inductive survey of eighty uncivilised peoples (forty-seven zoistic, twenty-one manistic and ten

deistic, two uncertain) establishes a definite relation between degree of sexual continence and cultural condition. The data show, he thinks, that all the peoples who allow pre-nuptial sexual freedom are in the zoistic cultural condition; that all the peoples who impose occasional or irregular continence are in the manistic phase; that pre-nuptial chastity is accompanied by the deistic cultural condition, and that in each class of cases the converse propositions may also be shown to be true He concludes that cultural condition and sexual opportunity are not only definitely associated in the manner indicated, but also that the relation is a causal one, the reduction of sexual opportunity providing the energy required for cultural change The transition from association to causal connexion is effected by an appeal to psycho-analysis, which has independently arrived at the conclusion that civilisation or culture has depended upon a restriction or repression of the sexual impulses and a diversion of libidinal energy

Dr Unwin has handled his material with great skill, and his induction may possibly be true Nevertheless, the methods which he has employed seem open to serious objections First, to judge social energy by reference solely to the way in which a people behaves to the mysterious powers in the universe seems arbitrary procedure, when no account is taken of their arts and crafts, their power of organisation, their skill in war, in trade or generally in the control of natural forces Even in the magico-religious field proper, the criteria employed are of doubtful adequacy Secondly, difficulties arise from the relatively small number of cases utilised in the survey No doubt Dr. Unwin was hampered by the poverty and vagueness of the anthropological material He asserts that, so far as his knowledge goes, the behaviour of the societies that he has omitted from consideration does not militate against his induction But in a matter so controversial and in the absence of corroborative evidence from other fields of social energy, his induction rests on a precarious basis and might be shaken by a broader survey This applies especially to his deistic societies, of which Dr. Unwin enumerates only ten cases, particularly as the evidence regarding pre-nuptial relations is doubtful regarding three or four of them. Thirdly, the method that Dr Unwin employs is that which a logician would describe as that of agreement and difference The validity of conclusions so drawn depends upon the elimination of alternative causes But this Dr. Unwin makes no attempt to do. He does not inquire, for example, whether the prohibition of pre-nuptial relations is correlated with the prevalence of marriage by purchase or other features of the family structure, or again, with the general development of law in other spheres of behaviour.

Finally, Dr. Unwin's conclusions may to some extent be checked by reference to an inquiry conducted on different lines by the late Prof. Hobhouse, Mr G. C Wheeler and the present writer in 1915 ("The Material Culture and Social Institutions of the Simpler Peoples") There the attempt was made to correlate regard for chastity with cultural grade as measured by economic criteria, the peoples being classified into lower and higher hunters, two grades of pastorals and three agriculturals In the matter of pre-nuptial unchastity, we found no constant tendency, though the cases of condemnation were more numerous among the agricultural and pastoral peoples than among the hunters If other points relating to chastity are considered, such as the punishment of adultery and the prevalence of wife-lending, we found that, on the whole, there was an increasing tendency for the family life to be consolidated with advance in economic grading Owing to the vagueness of the evidence, however, we should hesitate to assert universal association between sexual regulation and economic conditions, still more any causal connexion. It may be added that Prof Westermarck, who has made a very wide survey of the evidence, concludes that there is no relation between the toleration of unchastity and the degree of culture, and that, on the contrary, chastity is more respected in the lowest tribes than in the higher ones

Upon the whole, my impression is that the evidence available in the present state of anthropology is neither detailed nor abundant enough to afford a satisfactory basis for a generalisation so far-reaching as that propounded by Dr. Unwin.

MORRIS GINSBERG.

Mineral Resources of the French Colonies

Publications du Bureau d'études géologiques et Minières coloniales. *Introduction aux Études Minières coloniales* Pp viii+349+9 plates. (Paris: Société d'Éditions Géographiques, Maritimes et Coloniales, 1934) 36 francs.

THIS volume follows up and forms part of a useful series of publications issued during the last two years or so by the Bureau d'Études géologiques et Minières coloniales on the subject of the mineral resources of the French Colonies. Its object is to give an account of some general aspects of the mining industry with which it is important that colonial miners and geologists should be familiar.

An opening chapter on the genesis of minerals is followed by one on laterite. These are followed

by chapters on alluvial deposits, geophysical prospecting, health, transport, native labour, microscopical studies of coal and metallic ores, commercial problems and the relation of France to its colonies with regard to the supply of metals

A consideration of these pages shows that France and her colonies are far from self-sufficient in their supplies of metals The apportionments of mineral resources among the nations of the world are singularly irregular. France has ample home supplies of iron, and therefore has no need at present for her large colonial output in north Africa, which goes largely to Great Britain and Germany We are reminded, however, that a half a century from now—a short time in the history of a nation—a state of impoverishment in the supplies of iron ore from the eastern basin of France may begin to assert itself, and France may then need her colonial output of iron ore.

New Caledonia produces supplies of nickel matte amply sufficient for the needs of France, but it is curious to note that a large part of the output of this matte is sent to Great Britain, the United States and Belgium, and from these countries, none of which produces nickel ore, France has to import for her own needs considerable amounts of metallic nickel that has been made in part from New Caledonian matte.

The case of chrome ore is also interesting, for New Caledonia produces ample supplies of high-grade chrome ore, the production of which is controlled by foreign capital Only a small proportion of the output goes to France, whose further requirements have to be met by importing large amounts of chrome ore and ferro-chrome from foreign countries

Among other mineral supplies necessary for the metal industries, the French colonies have considerable resources of lead ore, zinc ore and graphite, but, so far as yet known, very little of the ores of manganese, copper and tin On the whole, the position as regards the output of metalliferous ores in France and her colonies compares quite unfavourably with the position in the British Empire

The eminent specialists who have contributed to different sections of the book include such well-known authorities as L de Launay, A Lacroix and A Lambert-Ribot The book is well indexed and illustrated, and makes a useful addition to the serviceable memoirs already issued by this very active Bureau.

Short Notices

Man versus Rabbit. By A. H B Kirkman (ULAWS Monographs, No 4b) Second edition, entirely rewritten Pp vi+74+9 plates (London: University of London Animal Welfare Society, 1934) 1*s.*

ONLY those who live in the country can properly appreciate the damage done by rabbits, where they are at all numerous. As all gardeners know, the losses they inflict in the course of the year are both serious and exasperating; and farmers, in many parts of the country, suffer even more severely. Mr Kirkman, then, has done us great service by presenting in this small volume an able and impartial summary of the methods of 'farming' rabbits for the market, on one hand, and their destruction as 'vermin' on the other From whichever of these two aspects they are regarded, the manner of their slaughter is an issue of the first importance, which forms the main theme of Mr. Kirkman's book. Its aim is to secure legislation to prohibit the use of steel-traps He has shown how ineffective they are for their avowed purpose of reducing the rabbit-pest, as well as the harm they do—apart from the cruelty which attends their use—in killing or maiming other animals more or less directly useful to man

With praiseworthy fairness Mr. Kirkman has cited the views of those who are still in favour of the use of the steel trap. But against them he arrays overwhelming evidence of landowners, game-keepers, farmers and gardeners who deplore their use, employing instead ferrets, nets or gas, according to circumstances. Some may object even to these measures But we must not let 'humanitarianism' become an obsession. For there can be no doubt that these animals are a grave menace to both gardener and farmer There are comparatively few of those whose crops are now so seriously menaced, or among sheep farmers, who would not welcome an Act of Parliament forbidding the use of steel-traps for any purpose whatever

Evidence is given by Mr Kirkman to show that, as a means of reducing the rabbit-pest, steel traps are worse than useless, for they kill vastly more bucks than does The reason for this differentiation is unknown, but it is suggested that the does wander less and are more timid and suspicious This is only one of many surprises that have come to light in the course of Mr Kirkman's investigations

We are glad to find that the author directs attention to the folly of an intensive war on stoats Besides their help in keeping down rabbits, they are extremely valuable allies in the war that, so far, is only half-heartedly carried on against rats. while the weasel as a mouse-destroyer is no less valuable

The Design and Construction of High Pressure Chemical Plant. By Harold Tongue. Pp ix+420+69 plates (London: Chapman and Hall, Ltd, 1934.) 30*s.* net.

ONE of the pioneer laboratories to study the application of high pressures in chemistry and chemical industry has been the Chemical Research Laboratory at

Teddington directed by Prof G T Morgan; there the author gained his experience and carried out pioneer work A pleasing feature of the work at Teddington has been the facility afforded to members of industrial firms to gain experience in the design and construction of high-pressure plant Their needs have given the author a clue as to those aspects of his subject in which information is of the greatest practical value

The book is essentially a chemical engineering treatise, and is therefore fully illustrated with pictures of actual plant and diagrammatic and detailed drawings The author has sought to collect together all the information pertinent to the subject Thus he deals with gas compressors, with the preparation, purification and cost of the industrial gases; with the design of pressure vessels, with the measurement of pressure, with valves, fittings and pipes.

High pressures, together with high temperatures, have set a number of new problems for the metallurgist, the creep of steel, embrittlement and the penetration by hydrogen have been new factors for study, and many unexpected difficulties have developed in the manufacture of large pressure vessels for high-pressure service Ammonia, methanol, the hydrogenation of fatty oils, of coal oils and of petroleum, are still the large scale pressure processes In addition, there is the high pressure oil cracking industry An ever increasing number of other products are being manufactured in high-pressure catalytic circulatory plants

There is a definite need for this book, which will be found to contain a good deal of information now published for the first time

The Ideas of Physical Chemistry By H McKay and H A C. McKay Pp x+301+8 plates. (London William Heinemann, Ltd, 1934) 7*s* 6*d*. net

This volume, published without preface, but dedicated to the authors' mother and grandmother, appears from the wrapper to have been written for the "layman" or "non-chemical specialist" It is there referred to as an introduction, in which the facts of physical chemistry are described in simple language which anyone can understand A perusal of the text gives the impression that the authors have attended a recent course of up-to-date lectures on physical chemistry, in connexion with which some modern textbooks were recommended for supplementary reading, and that they have then written up their lecture notes in twenty-seven chapters, in the optimistic expectation that lay readers will possess the same grounding in chemistry and physics as the authors had when they began the course, and will therefore be able to follow their summaries of the subjects thus selected. The impression that the authors are relying on second-hand information, and have not gone back to original sources for the material used in constructing the book, is also suggested by the diagrams which illustrate the text, since these are almost all 'blackboard sketches' On the other hand, seven plates, mainly of spectra, are admirably reproduced

The subjects dealt with are not easy to expound or to understand, and it is doubtful whether the lay reader will be able to follow with advantage a narrative in which so much is taken for granted; on the other hand, the serious student ought at least to select for supplementary reading books which are based upon first-hand contact with original sources; but there is perhaps an intermediate grade of readers to whom the present compilation will be useful, and the publishers have done their share in making the book attractive to them.

The Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland: with a Record of Publications issued during Session 1933–1934 Compiled from Official Sources: Fifty-first Annual issue Pp vii+164. (London. Charles Griffin and Co, Ltd, 1934) 10*s* net

The fifty-first annual issue of this well-known Yearbook is likely to be as invaluable as its predecessors. All the particulars are compiled from official sources, and therefore reliable Government departments as well as learned societies are represented, and information is given concerning address, membership, meetings and publications To facilitate reference, the societies are classified by subject into fourteen sections, and a good index is appended

It is gratifying to note that this reference book is receiving increased support The publishers deserve this encouragement, for the volume is well produced, and is full of useful information It should be on the shelves of all libraries, institutions, laboratories, etc, which are interested in any branch of science

Popular Handbook of Indian Birds By Hugh Whistler Second edition Pp. xxviii+513+20 plates (London and Edinburgh Gurney and Jackson, 1935.) 15*s* net.

A **review** of the first edition of this useful handbook to the birds of India was published in **Nature** of October 6, 1928, p. 533. The book is very good value for its price, which perhaps explains why the first edition was so quickly exhausted In that edition, 250 common Indian birds were described; in the second edition, 275 are described at length A new feature is the brief mention with short descriptions of a further 230 species The requisite number of extra illustrations have been added The whole text has been revised and brought up to date

Facts and Theories of Psychoanalysis By Dr Ives Hendrick Pp xi+308+xii (London Kegan Paul and Co, Ltd, 1934) 10*s* 6*d*. net

Dr Ives Hendrick gives here what is probably the best account of the present position of this art—psychoanalysis can scarcely be said to have reached the position of a science yet The book is divided into four parts dealing with the facts, theories, therapy and present status of psychoanalysis. The author is largely a Freudian, and so does not approve of the theories of Adler, although to many in Great Britain the latter are more acceptable; but then the theories are not psychoanalysis as it ought to be understood as referring purely to Freudian theory.

Television in Great Britain*

THE report of the Television Committee under the chairmanship of Lord Selsdon, issued last week, seems to have taken the public and most of the experts by surprise, probably due to the fact that during the last nine months, when the Committee was sitting, they had heard practically nothing about television, and the low definition broadcasts that were given did not seem to be of much permanent value In particular, they find it difficult to believe the following extract from the report. "The time may come when a 'sound' broadcasting service entirely unaccompanied by television will be almost as rare as the silent cinema film is to-day," although the Committee modifies this slightly by saying that, in general, sound will always be the most important factor in broadcasting The promotion of television, therefore, will not hinder the continual development of sound broadcasting

Recent advances have contributed largely to the development of a technique whereby the scene to be televised is first photographed on ordinary cinematograph film It is then developed and scanned by light transmitted through it, and this system is used to provide a method of 'delayed' television when direct scanning by a mechanical device would be difficult or impossible Equipment is now available in which the cine-camera is connected with the film scanner The film after exposure is fixed, washed and partially dried It then passes through the scanner, and after further drying is stored for future use if required In this way, the new methods of producing rapid and sensitive emulsions for photographic processes have overcome the difficulties due to the comparatively feeble sensitivity of photo-electric cells

The direct scanning of open-air scenes and studio subjects is now possible without using abnormally powerful illuminating devices This is done by cathode rays in combination either with minute photo-electric cells or photo-sensitive surfaces One such device is being developed in the United States, Germany and Great Britain. The image to be televised is focused by means of lenses on to a photo-electric mosaic contained in a cathode ray tube. The cathode ray beam is directed on the surface of the mosaic, and by a method of magnetic control the image is scanned repeatedly. Electrical energy is thus drawn off from the photo-electric mosaic by the cathode ray which is proportional to the light intensity of the picture, and can be transmitted to operate the distant television receiver. The Committee definitely states that satisfactory reproduction of outdoor moving scenes can now be attained by this method when the visibility conditions approximate to those under which satisfactory cinematograph pictures can be taken It is assumed that the recording apparatus can be located reasonably close to, and at a moderately constant distance from, the scene which is being televised It is stated that, even in this stage of development, satisfactory reproduction can be obtained of such scenes as a procession, a lawn-tennis match and the finish of a horse race The transmission of the view of the whole course of a race or similar event would doubtless present much greater difficulty

On the day following the publication of the report, Baird Television Ltd gave the first public demonstration of the system as it will be used in the home when the new ultra-short-wave transmission by the B B C begins next autumn The demonstration was given in Victoria Street, and the Baird transmitters were at the Crystal Palace, a distance of about 10 miles, the wave-lengths used being 7 metres for vision, and 8 5 metres for sound Two receivers were shown, the sizes of the screens being 12 in × 9 in and 8 in × 6 in respectively There were about fifty people present and they could see both screens, sometimes the room was darkened, but at other times it was illuminated by ordinary light, the difference in the visibility of the pictures in the two cases being slight

The larger of the two receivers had to be adjusted several times during the performance, but the smaller one was not touched We first saw a 'close-up' of the announcer It was quite a good picture and easily recognisable—quite as good as the pictures seen in the poorer cinemas He said that the demonstration was to prove that the television of pictures of high definition over a large area is a practical reality, and that the reception of such programmes in any part of the Greater London area is possible by a Baird receiver This area has a population of more than ten million people He contradicted the assertions recently made that with ultra-short wave-lengths (4–8 metres) the maximum range is 5 miles With the present arrangements, satisfactory results are obtained up to 30 miles from the transmitter The interference trouble, sometimes produced by motor-vehicles, has been successfully overcome There was no trace of it in the pictures shown in the offices in Victoria Street on a busy afternoon.

The second item in the programme was given by Miss Alma Taylor from the Crystal Palace. She showed some new fashions in hats and various styles of hairdressing. She also, by means of a

* Report of the Television Committee. (Cmd. 4793.) Pp. 27. (London. H.M. Stationery Office, 1935.) 6d. net.

telephone, entered into an animated conversation with a member of the audience This was real television; we saw and heard two people talking together at a distance of ten miles. We next saw an out-of-doors horse-jumping and racing competition taking place on the terrace of the Crystal Palace A boxing match was then shown in one of the studios at the Crystal Palace with the attendant crowd and the noise and cheers These two were done by 'delayed' television A proof was given that the interval between the occurrences and seeing them on the screen was 35 seconds Excerpts were also given from several of the well-known Gaumont-British films including "I was a Spy" and "Jack Ahoy" The singing and the sounds of the dancing were reproduced excellently and the flickering was scarcely noticeable although a picture frequency of only 25 pictures per second was used A complete "Mickey Mouse" film was shown and was almost as good as those shown in the cinemas.

After seeing this demonstration, we agree with the Committee that there is good entertainment value in high-definition television accompanied by sound We also agree that in general the sound is the more important factor in broadcasting

Owing to the close relationship which must exist between sound and television broadcasting, the B B C is obviously admirably suited to be the operating authority The following advisory committee has been appointed to advise the Postmaster-General on points arising in connexion with television and to exercise control over the actual operation of the service Lord Selsdon (chairman), Sir Frank Smith, secretary of the Department of Scientific and Industrial Research, who will be chairman of a technical sub-committee, Col A S Angwin, assistant engineer-in-chief of the Post Office; Mr N. Ashbridge, chief engineer of the B B C, Vice-Admiral Sir Charles Carpendale, controller of the B B C; Mr F. W Phillips, assistant secretary of the Post Office

The transmission of high-definition television is practicable only with ultra-short waves, for a wide band of frequencies is required. Fortunately, there is no difficulty at present in allocating suitable wave-lengths—between 3 and 10 metres—for public television in Great Britain Technically, it is desirable that the transmitting stations should be situated at elevated points The mast at present in use in Berlin is 430 ft high, and the question of employing masts of greater height is being discussed in Germany The Crystal Palace site of the Baird Television Company was chosen because it is the highest point in London The top of the south tower of the Crystal Palace is 680 ft. above sea-level, and the Baird aerials on the top of the tower give the maximum possible range of any site in the Greater London area The premises taken over by the Company cover an area of 40,000 sq. ft and are all on one open ground floor

The Committee has come to the conclusion that a start can best be made with a service of high-definition television in London It points out that there are two systems of high-definition television which are in a relatively advanced stage of development One of these is owned by Baird Television Ltd and the other by Marconi—E M I (Electric and Musical Industries) Television Co, Ltd The Committee suggests that an extended trial of these two systems be made under strictly comparable conditions They will be installed side by side in a London station and will issue programmes alternately and not simultaneously Among the conditions imposed are that the price demanded must be considered reasonable by the advisory committee and that the B B C be indemnified against any claim for infringement of patents The definition also should not be inferior to a standard of 240 lines for scanning and 25 pictures per second The present experimental transmission gives 30 lines per picture and 12½ pictures per second The pictures are 'coarse' in texture, and the flickering is objectionable

The Committee looks forward to the time when there will be a general television service throughout Great Britain Television broadcasts will be relayed by land line or by radio to substations in various parts of the country Owners of sound receiving sets will be glad to hear that, during the first experimental period at least, the cost of the new transmission will be borne by the revenue from the existing 10s license fee Afterwards a reasonable share will have to be contributed by the Treasury and the Corporation

The smaller of the complete sound and vision receiving sets made by the Baird Television Company is a cabinet 4 ft high, 2 ft wide and 2 ft. deep. The size of the picture is 8 in. × 6 in, and it is sufficiently brilliant to be seen quite clearly with ordinary room lighting It can be used with any type of high-definition transmission having 100–500 lines and 12–50 pictures per second. It can be seen by ten people in a room quite comfortably. It requires little skill to operate. The selling price will be at first about £50, but when bulk production has been started it is likely to be reduced considerably As it is operated on ultra-short wave-lengths, there is no trouble with atmospheres The Company also produces a larger set suitable for an audience of thirty people and having a screen 12 in × 9 in. These sets are not likely to become obsolete by changes in transmission technique during the next four years The price will be at first about £80.

Social and Industrial Aspects of Scientific Research*

IT is difficult to imagine a document which better illustrates alike those social aspects of scientific research to which attention has been repeatedly directed in recent months, at the British Association meetings or elsewhere, and the way in which the direction of scientific research is itself determined by the needs of the community, than the nineteenth annual report of the Department of Scientific and Industrial Research which was issued on February 2 This report covers the period October 1, 1933, to September 30, 1934, and contains the brief report of the Privy Council Committee, signed by Mr Stanley Baldwin, the longer report of the Advisory Council over Lord Rutherford's signature, and summaries of the work of the National Physical Laboratory, the Chemical Research Laboratory, the various research associations and research boards Certain of the latter issue their own independent reports, but no one document issued by the Department gives such a comprehensive and lucid account of the way in which the Department of Scientific and Industrial Research serves our national life, whether in departments of State, industry or the social needs of a civilised community

The expenditure of the Department during the year ending March 31, 1934, was £664,482 gross, or £476,897 net, as compared with £451,987 net in 1932–33 Receipts decreased, however, from £202,749 in 1932–33 to £187,585 This latter sum includes £59,774 in fees for paid work for industry , £10,209 representing contributions from industry for co-operative research, and £99,705 from other Government funds, including a payment of £21,520 from the Road Fund for building and road research and a grant-in-aid of £30,000 from the Empire Marketing Board for food investigation. Net expenditure on the National Physical Laboratory was £118,687 , on the Chemical Research Laboratory, £22,164 ; building and road research, £29,684 , food investigation, £10,707 , forest products research, £33,911 , fuel research, £80,423 , and water pollution research, £5,453 The Geological Survey and Museum received £63,426 and research associations a total of £58,992

Particular stress is laid in the report of the Advisory Council upon the efforts made to improve the position of the research associations, as regards both obtaining greater financial support from industry and also securing the greater financial stability which is essential if long-range researches are to be undertaken and reasonable prospects of a career offered to the scientific staff. This appeal for further support from industry is not, however, based solely on the prospects of future benefits. It rests equally on the results already achieved, and stress is once more laid on these other ways in which science can assist industry by the application of existing knowledge and by the extension of the scientific method and outlook

An encouraging sign of the growth of this spirit in industry is seen in the expansion of those researches undertaken by the Department with the financial co-operation of industry As an example of such arrangements during the year may be mentioned the research on such questions as the effect of waves on resistance and pitching of ships and their propulsion, the effect of wind resistance, the behaviour of rudders and the improvement of propellers, which are carried out in the William Froude laboratory of the National Physical Laboratory This work, which is of fundamental importance in the design of new ships, is financed as to one half by industrial subscriptions

Other examples of such co-operative research are found in the investigations, also at the National Physical Laboratory, bearing on the practical development of steels for use at high temperatures, as in the turbine or in chemical engineering, investigations at the Building Research Station covering the safety factors of steel-work, the discovery of British sources of materials for increasing the resistance of concretes and mortars to chemical attack, the effect of sea-water on concrete, problems of driving concrete piles, welding in steel structures, and the continuous study of heating and ventilating problems throughout the year in a 'controlled weather' house which is now being erected through the financial co-operation of industry secured through the Institution of Heating and Ventilating Engineers.

The bearing of this co-operative work at the Building Research Station on the housing question needs no emphasis It is, however, worth noting that the introduction of new materials and the displacement of obsolete regulations offer most hopeful lines of radical development in the building industry, and both alike depend on the continuous application of scientific research. The survey, conducted by the Building Research Station and the Fire Offices Committee of the fire insurance offices, of the problems of testing building materials for their resistance to fire, is overcoming difficulties in the way of provision for fire-testing stations where large-scale experiments can be conducted.

Building research in fact figures prominently in the report. Proposals made by the Advisory Council are concerned with an expansion of the

* Department of Scientific and Industrial Research Report for the Year 1933–34 (Cmd 4787) Pp. iv+192 (London H M. Stationery Office, 1935.) 3s. net.

activities of the Station whereby the results of research and investigation would become available at an earlier date and also with the special problems involved in the construction of flats These include investigations on fire risks designed to test whether regulations in Great Britain are too restrictive or not, and others relating to the transmission of sound through the structural elements or through floors and partitions.

From housing questions it is an easy transition to problems bearing on food supply, and here the work of the Department affords a striking example of scientific co-operation with the Dominions overseas Even the brief summary contained in the Advisory Council's report indicates our immense debt in this field to Sir William Hardy, and the work of the Food Investigation Board is steadily growing in importance At the Covent Garden laboratory there is a full-time officer, experienced in the examination of experimental consignments of fruit and vegetables sent to Great Britain, whose services are also available for Dominion and Colonial Governments A definite advance has been recorded during the year in the application of gas-storage to shipments of chilled beef from Australia and New Zealand and a modified method of stowage has been developed which promises to be more effective and economical

Investigations in this field range over almost every type of foodstuff A storage atmosphere has been worked out, for example, in which the characteristic flavour of Cox's Orange Pippin apples can be retained during six months' storage Experiments at a Wiltshire factory have shown that rapidly growing pigs are more suitable for bacon production than slowly growing pigs With lighter salting supplemented by cold storage, a method of cure has been evolved which produces salted herrings more delicate in flavour and more suited to the modern palate than those previously available Problems of the herring industry have also been considered, and the discovery that herrings, frozen in brine at $-20°$ C, make good kippers after four months' storage at that temperature, which is now being tested on a semi-commercial scale, may enable supplies to be carried over from periods of glut to the times of shortage experienced particularly in winter

Besides the Food Investigation Board, several of the research associations are concerned with investigations on foodstuffs The Research Association of British Flour Millers is studying the reasons for one flour giving better bread and dough than another, and developing methods of measuring the physical properties of dough The Research Association for the Cocoa, Chocolate, Sugar Confectionery and Jam Trades has indicated methods for preventing boiled sweets being reduced to a sticky mass by the absorption of moisture and has also suggested modifications in the composition of such sweets to prevent coalescence under the influence of heat.

Turning from food to clothing, we are still within the field in which the activities of the Department touch the home The British Boot, Shoe and Allied Trades Research Association has done much to improve footwear service by providing knowledge which makes shoes more hygienic and comfortable, while the Leather Manufacturers Research Association has given a good deal of attention to the prevention of mould growth on leather The Wool Industries Research Association's new process for unshrinkable wool, yarns and fabrics is being exploited under mill conditions, and materials should be available for the public early in this year New motor fabrics from wool and rubber latex are also being introduced to the public The Linen Industry Research Association has investigated the behaviour of linen under repeated launderings, and other research in this field is undertaken by the Launderers' Research Association

Leaving the home we come naturally to transport, where the Road Research Station is responsible for fundamental work on road construction, which has a vital bearing on safety on the roads, skidding problems and lighting problems are both being investigated.

Space permits not even the briefest reference to many other ways in which the work of the Department of Scientific and Industrial Research is affecting almost all our public services—power, water, lighting, gas, fuel—and steadily raising their efficiency Mention should, however, be made of the work of the Forest Products Research Laboratory on Empire timbers, of investigations on the detection of toxic gases and the production of cheap and efficient respirators for use in industries where dust is a menace to health, investigations on cylinder wear of internal combustion engines—probably the most important cause of deterioration in the engines of motor-cars—radio research on the propagation of waves and long-distance transmission, dental investigations, illumination research, investigations on lubricants and on atmospheric pollution, if only to illustrate the immense range of activities of this one Department. Nor should it be forgotten that, in the various institutions aided by the Department, new instruments and methods are continuously being developed by which the control of existing processes or the solution of urgent problems is being achieved The interpretation and exposition of the record of work contained within the covers of this report is a task to which every scientific worker might well address himself.

Obituary

DR F A. DIXEY, F R S

FREDERICK AUGUSTUS DIXEY commenced his scientific career as a medical man and took the degree of B M., B Ch , Oxon, in 1884, followed by the D M. in 1891 He was for a while demonstrator in physiology at University College, London, and also at Oxford from 1883 ; and a histological preparation made by him was used for an illustration still reproduced in Quain's "Anatomy" But it was as an entomologist that Dixey will be remembered . his first entomological publication was on the phylogenetic significance of wing markings in certain Nymphalid butterflies, and until his death on January 16, in his eightieth year, he was associated with the study of evolutionary entomology at Oxford, so intimately bound up with the name of Poulton

Dixey was a true Darwinian and supporter of the current theory of mimicry as produced by natural selection He especially studied the Pierinæ, or 'white' butterflies, on which he became an acknowledged expert, and made two subjects particularly his own Fritz Muller in 1878 had shown that two distasteful species might benefit by resembling each other "they may even have gone to meet each other" he wrote , but Müller did not develop this theory. Dixey approached the subject independently through practical study of specimens and, in an important contribution on the phylogeny of the Pierinæ following on the lines of his first paper, he introduced in 1894 the term 'reciprocal mimicry' to express the production of a superficial likeness between distasteful forms of widely removed affinities by the apparent interchange of characters peculiar to each This term was superseded by 'diaposematism' to bring it into conformity with others used by Poulton The theory of Muller and its important extension by Dixey were controverted by G A K Marshall on statistical grounds , but R A Fisher in 1930 stated that Marshall's arguments were untenable

"The Relation of Mimetic Patterns to the Original Form", followed by "Mimetic Attraction" (1896-97) showed the successive steps through which a complicated mimetic pattern could be evolved in simple and easy stages from a form presenting merely the ordinary aspect of its own genus, and that the process of gradual assimilation, starting from one given point, may take several divergent paths at the same time In other words, the members of a single group may assume several different mimetic developments, each one corresponding to a distinct model, but all derived by easy stages from the same original form

A characteristic of natural selection is the production of one effect by different means, and in a study of mimetic butterflies of New Guinea, Dixey showed how a certain type of coloration was produced by spot and stripe markings the position of which, different in absolute detail, resulted in a uniform appearance relatively to the whole exposed surface of the wings.

Dixey was convinced of the importance of studying geographical distribution in its relation to mimicry, and made this the subject of his presidential address to Section D (Zoology) of the British Association in 1919 Coincidence, sometimes invoked to explain mimicry, can produce resemblance, and, in the guise of *advocatus diaboli*, he demonstrated examples from different parts of the world bearing similar patterns But such resemblances are crude, and lack the perfection of detail of typical mimicry, and thus coincidence fails to explain the latter

Seasonal forms of butterflies and the possible direct influence of climate were the subject of Dixey's second address, on "Entomology and Evolution", to the Entomological Society (now Royal) of which he was president in 1909–10 He maintained that the Lamarckian interpretation of the effect of climatic conditions was not justified "the modification is not inherited from the soma of the parent but is consequent upon the direct action of this external influence upon that parent's germ plasm".

Dixey's other favourite subject, in which he will long be recognised as a master, was the study, in Pierinæ, of specialised scent-producing scales to which Fritz Muller had directed attention in 1877–78 He found in 1899 that the peculiar scent of a male 'green-veined white' (*napi*), which had long been known to exist, could be detected on a brush used for removing scales from the wing, and in 1904 wrote that the scent of male butterflies is associated with specialised scales, confined to that sex, which can be removed from the wing and their odour perceived Such scales are confined to the upper surface of the wing, and may be aggregated to form scent-producing organs supplied with air by special tracheæ. These studies culminated in a memoir (1932) containing 437 drawings of scent-scales in different species of Pierinæ

At the time of his death Dixey had commenced the final copy of a paper on specialised scales on a portion of the wing of an American Pierine which, it is hoped, may be published as a posthumous contribution The investigation of special scent-producing structures, carried on by Dixey, has been splendidly developed along different lines, following Fritz Muller's suggestion of 1877, by H Eltringham. Elaborate apparatus on both wings and abdomen of male Danaine butterflies have been minutely described, and their use in the field has been witnessed by more than one observer. Further developments have resulted in the discovery of an intricate scent-producing apparatus on the head of a minute 'caddis-fly', and specialised glands, the function of which is unknown, are being discovered on many different parts of the body in insects of diverse kinds

Dixey returned to histology in 1931, and published an account of the development of wings in Lepidoptera.

Dixey was elected a fellow of the Royal Society in 1910, and was vice-chairman of the Association of British Zoologists : he was a familiar figure at meetings of the British Association, and played a genial part in the social gatherings

G. D. HALE CARPENTER.

Sir William Slingo

The death on January 19, at the age of seventy-nine years, of Sir William Slingo marks the passing of a distinguished civil servant and engineer, whose career has been associated with wide and far-reaching developments in the art of communication

At the age of fifteen years, Slingo entered the Post Office as a telegraphist, and twenty-eight years later was appointed to the Engineering Department, from which he eventually retired as engineer-in-chief in 1919 after a career in the civil service of nearly fifty years. During that period, which covered the growth of the trunk telephone system, the transfer of the National Telephone Company's plant to the State and the subsequent developments of telephony in Great Britain, Sir William Slingo played a very active part He was primarily responsible for the compilation of an inventory of the National Telephone Company's plant on its acquisition by the State On the basis of this inventory, an award of 12½ million pounds sterling was made to the Company instead of the twenty one millions claimed

Although at the outset Slingo was a telegraph engineer, at an early stage he proceeded to widen his outlook on telephone problems, and made substantial contributions to other branches of electrical engineering He was responsible for the design and installation of one of the earliest electrical lighting plants in London, when he acted as consulting engineer to the Drapers Company for an installation at the East London People's Palace

To Sir William Slingo's credit must be placed the achievement of building up the nucleus of an engineering staff from a group of telegraphists whose previous training was mainly that of manipulative skill In doing this, he first made himself proficient in the art, and then for many years carried on single-handed the pioneer work of training the telegraph engineers of the future He founded on his own initiative at the General Post Office, the Telegraphists School of Science, beginning with a handful of students, which had grown to 850 when he relinquished the post of principal Many engineers of established reputation in the art of tele communications received their earliest training in that school. Sir William Slingo's work during this period in furthering the study of telegraph and telephone engineering and placing it on a more scientific basis, at a much earlier date than otherwise would have been the case, exercised a wide influence, and, particularly in the devolopment of telegraphy, British practice was largely followed in other countries

After his retirement from the Post Office, Sir William continued to be actively engaged on communication work. Amongst other enterprises, on behalf of the Marconi Company he had acted as administrator general for the Peruvian system of posts, telegraphs and wireless services, a system which he reorganised and placed on a sound basis.

Sir William's professional reputation as an engineer was of the highest, but it is probable he will be best remembered and honoured by his early services in the training of telegraph engineers. A S A.

Dr John Howard

Dr John Howard, of the Fuel Research Station, Greenwich, was killed on January 3 through being caught by an avalanche and swept down a hillside in the neighbourhood of Vent His companion was Mr Kenneth F Armstrong, who was also killed Dr Howard was the only son of Mr and Mrs Fred Howard Mr Fred Howard was formerly Mayor of Holborn

John Howard was born in London and educated at Oundle School, where he specialised in history before going over to the science side, and was head of Sydney House In 1927 he became a scholar of Corpus Christi College, Oxford, and took his B A degree in 1930 and B Sc in 1931, being 'proxime' in the Gibbs scholarship in chemistry His work was directed by Dr Hammick, with whom he later published two papers Whilst at College he became sergeant in the artillery battery of the Oxford University Officers Training Corps and obtained his Certificate B In 1931 he gained a Commonwealth fellowship and worked at Princeton University with Prof H S Taylor upon "The Adsorptive and Catalytic Properties of Chromium Oxide Gel". He submitted a thesis on this subject and was awarded his Ph D. He published papers in association with Prof Taylor. He took an active part in a number of sports, particularly in swimming, rugby, fives and shooting He was captain of the school shooting team at Oundle and won the Stock Exchange Cup for shooting while at Oxford.

Dr Howard was appointed to the staff of the Department of Scientific and Industrial Research in 1933, and was assigned for duty at the Fuel Research Station, where he commenced an investigation to determine the causes of the deterioration of catalysts in the hydrogenation process He took a very broad view of the study of science, and his knowledge of history, which was inspired by his mother, who was a graduate in history at Manchester, aroused his interest in the general trends taking place in the fuel industry. As a result he was concentrating upon the effects of the economic changes upon the devolopment of the uses of fuel, and he was acting as the personal assistant of the Director of Fuel Research. He had a very good knowledge of languages and had taken up the study of economics. He had a charming personality and had established a real friendship with his colleagues on the staff

---

We regret to announce the following deaths.

Prof Oliver P Jenkins, emeritus professor of physiology and histology in Stanford University, an authority on American fishes, on January 9, aged eighty-four years

Prof Hugo Junkers, founder and until 1932 head of the aircraft firm of that name at Dessau, who was a pioneer in the development of all-metal aircraft, on February 3, aged seventy-six years

Prof. Emanuele Paternò, formerly professor of general chemistry in the University of Rome, and an honorary fellow of the Chemical Society.

News and Views

Planetary Atmospheres

WE are glad to be able to publish as a special supplement this week a survey of existing knowledge of the atmospheres of the planets, which formed the subject of the presidential address delivered by Prof H N Russell at the recent Pittsburgh meeting of the American Association Prof Russell is known to all astronomers for his work on stellar development, and particularly by his division of stars into the two types of 'giants' and 'dwarfs' in which the temperature is rising and falling respectively In recognition of this and other contributions to astrophysics, he was awarded the Gold Medal of the Royal Astronomical Society in 1921, and he has been similarly honoured by a number of other leading scientific societies In his address Prof Russell first points out that the presence of atmospheres on Jupiter, Saturn, Mars and Venus was proved, many years ago, by telescopic observations of clouds, polar snow-caps and twilight The moon has no trace of atmosphere, nor has Mercury The spectroscope enables information about the composition of these atmospheres to be obtained, but it will not detect hydrogen, nitrogen, helium or other inert gases in such atmospheres Tests for oxygen and water-vapour are complicated by the presence of these substances in the earth's atmosphere By taking advantage of the Doppler shift of the lines when a planet's distance is changing rapidly, this difficulty can be escaped The latest observations at Mount Wilson show no traces of oxygen or water-vapour, either on Mars or Venus The small amount of water required for the Martian polar caps might escape detection Bands due to carbon dioxide have been discovered in Venus, and they indicate a layer of the gas at least two miles thick. The major planets show other bands—increasing in strength from Jupiter to Neptune—all due to methane (CH_4) the simplest hydrocarbon Ammonia gas gives weaker bands in Jupiter and Saturn

PHYSICO-CHEMICAL explanations are available for these facts Small bodies, such as the moon, have not sufficient gravitational attraction to prevent their atmospheres from escaping into space. Middle-sized planets, like the earth, probably lost almost all their initial atmospheres while they were in process of formation, and intensely hot. As the rocky crust solidified, water vapour and carbon dioxide would escape from it and be added to the residual nitrogen, argon and neon. The free oxygen on the earth is probably a product of plant life. Venus appears to be a planet on which life did not start—leaving the carbon dioxide unaffected Large planets would retain hydrogen and all other gases. There is a great excess of hydrogen in the sun If the same were true of the planets, they would cool down into rocky cores, surrounded by oceans thousands of miles deep, and then by atmospheres highly compressed by their own weight. The chemical equilibria in such mixtures have been carefully studied, as they are of industrial importance. At high temperatures and low pressures, hydrogen, nitrogen and carbon dioxide would prevail—at low temperatures and high pressures, hydrogen, methane, ammonia and water The surface temperature of Jupiter is about − 120° Centigrade, and the ammonia is on the point of condensation, probably forming the clouds visible in the planet Saturn is colder, and almost all the ammonia is frozen out In Uranus and Neptune it is completely gone, enabling us to look deep into the atmospheres of hydrogen and methane, which must be very extensive

Inland Water Survey

THE Minister of Health (the Right Hon Sir Hilton Young), and the Secretary of State for Scotland (the Right Hon Sir Godfrey Collins), have appointed a Committee to advise on the Inland Water Survey for Great Britain, on the progress of the measures undertaken and on further measures required and, in particular, to make an annual report on the subject The members are as follows: Col Sir Henry G. Lyons, F R S, Sir Charles H. Bird, Prof. W. S. Boulton, Mr G Dallas, Mr G J Griffiths, Lieut-Col F. Hibbert, Sir Clement D M Hindley, Mr S R. Hobday, Mr. W A. Millar, Mr D. Paul, and Mr. B Verity The secretary to the Committee is Mr. I F Armer, and any communications relating to the work of the Committee should be addressed to him at the Ministry of Health, Whitehall, S W 1. In constituting this Committee, it is stated that the object has been, not to appoint representatives of organisations or interests, but to obtain a body of men of different classes of experience serviceable for the work to be undertaken

THE class of experience chiefly represented upon the Committee is, however, that of water users; and we are disappointed that little attention seems to have been paid to the recommendations of the British Association Committee on Inland Water Survey by the Ministry of Health The need for a scientific survey of the water resources of Great Britain was brought out at the York meeting of the Association in 1932 through a paper in which Capt. W. N McClean described some of his work on river flow The result was the appointment of a strong committee, with Vice-Admiral Sir Percy Douglas, formally hydrographer of the Navy, as chairman, and Capt W. N. McClean as secretary. This Committee produced a valuable report, in which the scientific aspects of inland water survey were clearly presented. It is surprising, therefore, to record that not a single member of the British Association Committee, which was responsible for directing public attention to the whole subject and suggesting a possible programme of work, is included among the members of the Committee just appointed.

Commemoration of Prof. Haber's Death

WHEN Prof Fritz Haber died in Switzerland a year ago, we were glad to publish in the columns of NATURE an eloquent tribute to his greatness, written by one of his old pupils By the irony of political circumstances in Germany, the loss of this chemical genius was limited in the journals of that country to a bare announcement, and no obituary notice at all adequate to the influence of his life and work appears to have been published at the time It is not surprising, therefore, that Haber's scientific friends desired to honour his memory on the anniversary of his death, and that a number of them assembled for this purpose in the Harnackhaus of the Kaiser Wilhelm Gesellschaft on January 29, in spite of the official disapproval of the celebration to which we referred last week (p 176) The Berlin correspondent of *The Times* reported that the speakers at the meeting laid emphasis on Haber's devotion to his country and his scientific services Prof Max Planck, who presided, recalled that Haber's synthetic nitrate process had saved Germany from military and economic collapse in the first months of the War "We repay loyalty with loyalty," he said, and he laid particular emphasis on the last three words in his closing tribute to "this great scholar, upright man, and fighter for Germany" Prof. Otto Hahn, director of the Kaiser Wilhelm Institute for Chemistry, and other speakers also bore testimony to the debt owed by Germany to Haber for his outstanding contributions to pure and applied chemistry, and in doing so they expressed the feelings of their colleagues throughout the world It will be remembered that Haber resigned his post at Dahlem in the spring of 1933 and afterwards accepted an invitation of laboratory hospitality at Cambridge, where he went in October of that year He intended to reside there permanently but died at Basle, where he had gone for a short holiday, on January 29, 1934.

British Industries Fair

THE British Industries Fair, 1935, organised by the Department of Overseas Trade, is being held at Olympia and the White City, London, on February 18–March 1. This year the Engineering and Hardware Section is to be held at Castle Bromwich, Birmingham, not simultaneously with the London sections, as previously, but later, on May 20–May 31 The textile and furnishing exhibits will be shown at the White City and the general articles, other than engineering and hardware products, will be exhibited at Olympia There are 1,550 exhibitors at Olympia and the White City, of which more than 750 are from London There are again notable increases in the space taken and the number of exhibitors, compared with last year's figures An indication of the remarkable growth of the Fair is given by the fact that the advance catalogue, which is issued in nine languages, runs to 684 pages, or about 152,000 words. The exhibits of products of scientific interest at the Fair again cover a wide range and reveal markedly the increasing use of scientific products, both materials and instruments, in the field of industry The Committee responsible for the organisation of the united exhibit of scientific instruments is to be congratulated on the important display at Olympia of scientific, optical and photographic instruments. Microscope object-glasses of great refinement of construction; microscope projection apparatus; sound projection apparatus for cinemas, with suit-case sound sets for commercial and educational purposes; various forms of planimeters, pocket cameras and aircraft cameras, distant-reading thermometers; geophysical apparatus for prospecting for gold, minerals and oil—these are but a few examples, selected almost at random, of the products that are being shown in this united exhibit It is worth notice that, until two years ago, practically all the various forms of planimeters used in Great Britain came from abroad; and similarly, the particular geophysical apparatus referred to above was practically a German monopoly It is good to note the enterprise of British scientific instrument manufacturers in these new fields

Whales and Whaling

THE International Convention for the Regulation of Whaling, which came into force last month, is a first and important step towards the permanent preservation of whales and whaling Since whales are killed almost entirely outside territorial waters, any effective measures having these ends in view must be taken by all great whaling countries in common, and one of the most important aspects of this Convention is that it inaugurates international treatment of the whaling industry. The Convention is concerned with the whalebone whales, on which all but a small part of modern whaling is based. It prohibits the capture of right whales, which have been reduced in numbers almost to disappearance, and requires a far more thorough utilisation of the carcases of other whalebone whales than was customary. A quite common practice was to produce oil from the blubber (from which oil is most easily obtained) alone The Convention requires the utilisation of specified parts of the carcase, in which it follows the whaling regulations of the Falkland Islands Dependencies, and recent Norwegian law Thus is economically sound, since it enables a given quantity of oil to be obtained from fewer whales There is reason for supposing that the whales so saved may in a single season reach some thousands. Lastly, the Convention provides for the collection and collation of the statistics of both capture and manufacture, which should prove of the greatest value in the development of a full and satisfactory regulation of whaling. It makes no provision for the limitation of whaling, and as this will probably prove essential if the industry is to be maintained, it is a step only towards the solution of the main whaling problem; yet it is a valuable advance, in which it is greatly to be hoped the few whaling States not at present signatories will soon see their way to participate.

The Hoover (Boulder) Dam

THE completion, just announced, of the great concrete structure originally known as the Boulder

Dam, but afterwards officially designated the Hoover Dam, across the Colorado River in Black Canyon, which forms the boundary between the States of Arizona and Nevada, at a point about twenty-five miles south-east of Las Vegas, Nevada, marks the attainment of an advanced stage in the execution of the notable Boulder Canyon Project, the Act for which was approved by the United States President in December 1928 The project in its entirety comprises not only the construction of a dam and the formation of an artificial lake, respectively the highest and the most capacious of their kind in the world, but also other incidental works involving an expenditure estimated at the time at 165 million dollars The probable outlay is now given as 385 million dollars The dam has a maximum height of about 730 ft, an extreme length of 1,180 ft, a crest width of 45 ft and a bottom thickness of 650 ft It contains about 4½ million cubic yards of concrete, and will be the retaining wall of a reservoir having a length of 115 miles and a total cubic capacity of 30,500,000 acre-feet It is designed to impound the flood water of the Colorado River for use in irrigation, and will serve to regulate the flow of that stream so as to improve its navigability, and protect the adjacent valleys from overflow, water shortage and silt accumulation Irrigation and protection from inundation of valuable farm lands in Southern California are the primary and essential objects of the undertaking, but hydraulic turbines of exceptional calibre are also being installed to enable electric power to be generated, the revenues from which will fully recoup the outlay on the entire scheme, which, including a main irrigation canal, 80 miles in length, with an extension 130 miles long to adjacent valleys, is among the most remarkable instances of engineering enterprise in modern times.

Anti-Noise Exhibition

THE Prime Minister will open on May 31 at the Science Museum, South Kensington, an Anti-Noise Exhibition which is being arranged through the Anti-Noise League The Exhibition will remain open throughout the month of June and probably conclude with a congress during the last week. The chairman of the League, Lord Horder, broadcast on the subject of the Exhibition on January 20. It is proposed that the Exhibition shall present a comprehensive survey of the whole problem of noise in its many aspects. The practical co-operation of a number of institutions and public bodies has already been obtained, including the Ministry of Transport, the Air Ministry, the National Physical Laboratory, the Post Office Research Laboratories, the British Broadcasting Corporation, the Industrial Health Research Board, and a number of industrial research laboratories Dr. G. W C. Kaye, of the National Physical Laboratory, is chairman of the Research and Development Section of the Exhibition, Prof. Cave-Browne-Cave, of the Transport and Machinery Section, Mr. Hope Bagenal, of the Building Section, and Sir Henry Richards, of the Organising Committee. The Science Museum has placed generous accommodation, including a cinema theatre, at the disposal of the Exhibition and it is hoped to display many interesting exhibits of noise abatement appliances A small silent house is to be erected which will incorporate the latest architectural and building designs and materials for sound proofing and sound absorption. There will be a number of demonstrations, including silenced pneumatic drills, motor-cycles, typewriters, vacuum cleaners, electric motors, circular saws and so on The latest devices for the measurement, analysis and filtering of noise will be shown, the psychological aspects of noise will receive attention, and experiments on the value of ear defenders, the masking of noises, the effect of noise on loudness of speaking and the use of noise level alarms will claim the interest of most people The effect of noise on output in industry will be illustrated by the results of recent investigations

The Microscope and the Metal Industries

DR C H DESCH delivered a Research and Development Lecture under the auspices of the Royal Institution and the British Science Guild on February 6, taking as his subject "The Microscope and the Metal Industry" Although a careful drawing of a metallic object (the edge of a razor) was published by Robert Hooke in 1665, it was two hundred years before any further use was made of the microscope in the study of metals H C Sorby, a Sheffield amateur, began in 1854 to apply the microscope to polished and etched surfaces of steel and succeeded in identifying correctly a number of separate constituents in the varieties of steel and cast iron available to him It was twenty years before these results attracted any attention, but from that time onwards, the microscope has become an indispensable tool in the metallurgical industry Specimens of metals are ground and polished, care being taken to avoid distortion, and are then etched by means of a suitable reagent which will distinguish between the various constituents All metals and alloys are built up of crystals, and the relative sizes of the component crystals frequently determine the properties of the mass With this object in view, systematic measurements of crystal size are made as metals are passing through the processes of manufacture The reading of a micro-section may be compared with the reading of a map, which conveys the more information the greater the experience of the person using it. A further important application of the microscope is in the study of failures The fracture of crankshafts and other moving parts by fatigue, the cracking of boiler plates and superheater tubes, the breakage of wire ropes, and the cracking of severely cold worked sheets, are typical examples of occurrences on which the microscope is capable of throwing light by indicating the nature of the processes concerned in the failure, and thereby giving a clue as to their origin The microscope has now become an essential part of the equipment of every works dealing with the production of metal, and also with the transformation of metals into useful products on a large scale

Electrical Development in Northern Ireland

AN experiment on the co-ordination of electricity distribution is now in its fourth year in Northern Ireland. With the exception of the areas covered by the county borough undertakings of Belfast and Londonderry and by the Antrim Electricity Supply Co., practically the whole of Northern Ireland is included By an Act passed by the Parliament of Northern Ireland in 1931, a Board was set up, the duties of which were to promote, co-ordinate and improve the supply distribution of electricity generally throughout the country The Act specially laid down that the Board should not be a profit earning body and that the members should not be financially interested in any company engaged in electrical work In a paper read to the Institution of Electrical Engineers on January 23, Mr. C R Westlake showed that the policy of co ordination is proving successful, and that the public now has a service of electricity supply not possible under the previous types of control. The main source of supply in Northern Ireland is the harbour power station of the Belfast Corporation, and the area round it is populous The area taken for primary development covers 1,200 square miles and has a population of about 300,000 The Board can purchase its supplies from any authorised undertakers, and it has adequate equipment to provide for rapid and continuous growth The problem is to supply energy at rates low enough to secure growth and at the same time to secure sufficient revenue Notwithstanding the competition of gas companies, more than 50 per cent of the potential consumers are already connected, and where there is no competition, 'saturation' is attained almost immediately. Whole areas hitherto without supply have now amenities usually associated with city life without loss of their rural surroundings This successful experiment shows the trend of public policy towards the co-ordination of all public utility undertakings.

Japanese Patents and Inventions

ON December 23, 1934, the *Japan Times and Mail* published a special "Invention Number" in connexion with the commemoration of the jubilee of the Japanese patent law The number contains much interesting matter regarding the birth and growth of the Patent Bureau, the increase in the number of patents applied for and sanctioned, and the place of Japan as a great industrial nation. The early history of the Patent Bureau, which in 1933 had a staff of 600, was dealt with in a broadcast address by the Minister of Finance, Mr K Takahashi, who was the first chief of the Bureau. The first law enacted by the Government for the protection of inventions, he said, was the so-called expedient monopoly regulations promulgated on April 7, 1871. This, however, was never enforced and in the following year was abolished. A special committee was next appointed to examine the British and American patent laws, and from its work sprang the first Trade-Mark Act in Japan, promulgated on October 1, 1884, followed by the Patent Act of April 18, 1885. This Act came into force on July 1, and No 1 patent was issued that day to a Tokyo citizen, Zuisho Hotta, for a coating material for ships and iron bridges For the first twenty years, patents and inventions failed to attract much public attention, and whatever progress was made in industry was due more to successful imitation of Western practices than to original discovery or invention From the time of the Russo-Japanese War, however, largely through the action of the body now known as the Imperial Invention Association, invention has been encouraged by the Government, and to day Japan now claims to rank only behind the United States and Germany in the number of patents granted In several of the contributions to the "Invention Number", recognition is given to the debt Japan owes to foreign countries, but there is also a just sense of pride in the status to which she has attained through her own initiative

Gas Warfare by Air

THE large number of publications in Germany dealing with all aspects of gas warfare which have appeared during the last two years is well known to all in touch with the German technical press, and increasing attention has been devoted to this matter in Great Britain also in recent months The pamphlet entitled "The Menace of Aerial Gas Bombardment", by Lieut -Col N. G Thwaites, which has now been issued by the *New Commonwealth*, is a welcome statement of the facts in a matter in which conflicting expert opinions have confused the public mind. Reviewing the situation in the different countries of Europe, Col Thwaites points out that the danger of gas attack from the air is taken very seriously by Germany, France and Italy, while Russia is openly preparing for chemical warfare In Germany no opportunity is lost of educating the public in anti-gas precautions, and a widely circulated "Handbook of Air Defence" was issued in May 1934. Equipment of the public with gas masks has not yet proceeded very far In France the public has been made aware of the danger of aerial gas attack, and gas masks are now being sold in large quantities after testing by the authorities In Italy, anti-gas precautions are dominant among the measures taken for defence against air attack, and the supply and distribution of gas masks has been carried further than in other countries, in Poland a League for Aerial Defence against Gas receives strong support from the Government

COL THWAITES proceeds to discuss briefly the measures being taken in Great Britain, as well as the probability and horrors of gas warfare. In his view, the defence measures so far taken are futile, and no merely technical remedy is likely to suffice for long. He considers that the only effective remedy is the abolition by mutual agreement of all national military air forces and the establishment of an international air force for policing purposes. The alternative policy of isolation is no longer possible and the present condition of air strategy puts a premium on the aggressor. The technical difficulties in the

The Atmospheres of the Planets*

By Dr Henry Norris Russell, Research Professor of Astronomy and Director of the Observatory, Princeton University, N J

Direct Telescopic Observations

As soon as telescopes became good enough to give a tolerable view of details on the planets, evidence began to accumulate that some of them, at least, possessed atmospheres Doubtless the first to be noticed were the changes in the markings on Jupiter, which differ radically from one year to the next, and often appear suddenly and last but a few weeks, though *thousands of miles in diameter Only clouds*, forming and dissolving in a Jovian atmosphere, can account for such rapid and capricious changes

Evidence for an atmosphere on Mars is afforded by the polar caps. The steady shrinkage of these during the summer, accompanied by the growth of the opposite cap during the long cold polar night, is explicable only by the melting or evaporation of deposits of some snow-like substance, which is carried as invisible vapour to the opposite pole, and there deposited. A permanent, non-condensible atmosphere is required for the transport of this vapour.

Venus, when it is considerably nearer to the earth than to the sun, shows a crescent phase, like that of the moon, and for the same reason As it comes more nearly into line between us and the sun, its crescent narrows, and the horns begin to project beyond their normal positions, so that it has been seen as three-quarters of a circle, and even as a thin bright ring, with a dark interior. This remarkable phenomenon can be seen only when Venus is within about a degree of the sun, and no chance to observe it again will occur until near the end of the present century; but it has been recorded in the past by several competent observers. Such an extension of the horns—and, above all, the ring-phase—can be explained only as effects of twilight; the illuminated atmosphere of the planet being visible across the narrow dark strip of its surface on the side farther from the sun.

For the three brightest planets, then, the presence of an atmosphere is proved by observation, in three quite different but equally conclusive ways, all of which were well known to astronomers before the end of the eighteenth century.

Later observations have added evidence of the same type—a few white spots on Saturn, appearing at irregular intervals of some decades, which change shape, shift and disappear as clouds would do; occasional though fugitive clouds, and a measurable effect of twilight, upon Mars; and elusive markings on Venus, which can be photographed only with ultra-violet light, and change greatly between one evening's observations and the next

The *extent of atmosphere can also be roughly* estimated from the results of direct telescopic observation The surface details of Jupiter (and of Saturn when any appear) may be seen, and photographed, close up to the limb, despite the very oblique angle of view. It is therefore evident that there can be no such extensive gaseous mantle as veils the earth. At least, there is none above the visible cloud surfaces of these great planets—how much there may be below is another matter The rarefied layer which exists, however, suffices to cut down the apparent brightness of the edge of the planets' discs The effect of contrast against a dark sky conceals this in an ordinary telescopic view, but the first look at one of these planets in strong twilight shows that it is actually of surprising magnitude.

There is more 'limb-light' on Mars, and there may be more atmosphere above the visible surface—the real surface, this time; but an atmosphere as thick as the earth's, even if free from clouds or haze, would produce a much greater effect.

For Venus the layer which produces the elongation of the crescent is remarkably thin, rising only about 4,000 ft. above the visible surface. But this represents only the part of its atmosphere which is hazy enough to be seen through the glare of our own sky close to the sun The top of the atmosphere must be much higher; and the bottom, if the visible surface is composed of clouds, much lower, so that its whole amount may be great.

The celestial body which we can observe in far the greatest detail tells quite another story. The moon, viewed telescopically, shows no more atmosphere—whether in the artist's or the physicist's sense—than a bare plaster cast illuminated by a powerful searchlight. Far more delicate tests are possible here than in other

* From the address delivered on December 31, 1934, at Pittsburgh by Dr. H. N. Russell as retiring president of the American Association for the Advancement of Science.

instances, and neither refraction nor twilight is present to the minutest degree. Our satellite is naked rock *in vacuo*. Mercury, too, appears to be without an atmosphere, though the evidence is less detailed.

Presence of Oxygen and Water Vapour

The existence of atmospheres on the majority of the planets—though not on all—is thus established by direct telescopic observation. To determine their composition, we must, as usual, have recourse to the spectroscope; but we meet with two difficulties.

In the first place, many possible atmospheric constituents show no selective absorption whatever in the region accessible to our study. Hydrogen, nitrogen, helium, neon and argon belong to this group, and are hopelessly beyond the reach of our investigation. Secondly, the other gases of the earth's atmosphere absorb too much for our advantage. The worst by far is ozone. Though present in but small amounts, and mainly in the higher layers, it cuts off the whole spectrum short of 2900 A., and deprives us of any hope of studying the most interesting parts of all celestial spectra.

Were we working in the infra-red, water vapour would be almost as troublesome. There are long stretches of the solar spectrum, within the range of present-day plates, in which we can find out little or nothing about the sun's own spectrum. The great wide lines of the water vapour bands, often overlapping, hide almost everything else. The band near 11500 A. is quite hopeless; that at 18000 A. would be worse, if our photographs got so far; one near 9600 A. is still very bad; while in those near 8200 A. and 7200 A. the solar lines can be picked out, with care, among their stronger telluric neighbours.

Oxygen reveals itself by a strong band, with very regularly spaced lines, at λ7594 (Fraunhofer's *A*), the weaker *B* band near 6867, and the much fainter α band at 6277. The terrestrial origin of all these lines is conclusively settled by two tests: first, their changes with the altitude of the sun (varying the air-path) and, for the water vapour lines, with weather conditions; second, the absence of the Doppler shift, due to the sun's rotation, when light from the east and west limbs is compared. The absence of even faint components of solar origin is explained by the high temperature, which dissociates such molecules completely. The intensities of these bands are in inverse order of the abundance of the molecules which produce them—an apparent anomaly, explained by the circumstances of their origin.

The ozone band is part of the main system of the O_3 molecule, and, like all such bands, is very intensely absorbed, a layer of the gas, at its worst, being as opaque as one of metal of equal mass per square centimetre. For water vapour, the main absorption bands lie far in the infra-red, and are very strong—those with which we are now concerned involve high harmonics of the fundamental vibrations. The coefficient of absorption, and the intensity of the bands, diminish rapidly with increasing order of the harmonics and diminishing wave-length.

The oxygen bands are produced by a 'forbidden' transition within the molecule, for which the probability of absorption is exceedingly small. This is why the whole mass of oxygen above our heads (equivalent to a layer two kilometres thick at standard temperature and pressure) produces absorption lines no stronger than the sodium vapour in a Bunsen flame an inch thick, which contains but a minute percentage of the vapour of the metal. The principal bands of oxygen, in the ultra-violet beyond λ1800, are so strong that light of shorter wave-length cannot be observed at all in air. The experimenter must put his whole spectroscope in a gas-tight case, and pump it out to an almost perfect vacuum.

In the visible spectrum, the portions cut out by oxygen or water vapour are very small in extent; but they come exactly in the wrong place—in other words, they hide, line for line, absorption by these same gases which might be produced in the atmosphere of a planet. If the planet's atmosphere was decidedly richer in either constituent than the earth's, we might detect the fact, for the lines in the planet's spectrum would be stronger than in that of the moon. Comparisons of this sort, however, must be made with great precautions. The moon and planet must be at the same altitude when the observations are made (to get equal air-paths). It is not safe, either, to observe the planet early in the evening and wait until the moon rises to the same height, for a change in temperature may have caused the precipitation of water out of the air, though the oxygen, of course, remains the same. With sufficient patience, a time may be found when planet and moon can be seen together, at equal altitudes, and observed almost simultaneously, with the same instrument.

Early observations of this sort were supposed to show the presence of oxygen and water vapour on Venus and Mars; but the careful and accurate work of Campbell, in 1894, led him to the conclusion that there was no perceptible difference in the strength of the bands in the two cases, and hence that the amounts of these two important substances, above the visible surfaces of either planet, did not exceed one fourth of those above an equal area of the earth's.

A more delicate, and very ingenious, test was invented, independently, by two distinguished

American observers, Lowell and Campbell. When Mars (or Venus) is approaching us, or receding, most rapidly, the lines in its spectrum are displaced, by the Doppler shift, while lines produced in the earth's atmosphere are, of course, unaffected. Were this shift great enough, the planetary and telluric lines would appear double, and the former, even though faint, could readily be detected. The greatest available shift is not enough to resolve the lines completely, but measures of the blended lines suffice to show whether any important planetary contribution is present. A still more delicate test is afforded by microphotometer measures of the contours of the lines, which would reveal even a slight asymmetry. These observations are very exacting—requiring high dispersion and a great deal of light—so that the best evidence is that from the great coudé spectrograph of the 100-in. telescope at Mount Wilson. St. John and Nicholson found, in 1922, that there was no perceptible trace of planetary lines in Venus, and Adams and Dunham, in 1934, have come to the same conclusion in the case of Mars. An amount of oxygen, on either planet, equal to a thousandth part of that above an equal area on earth, could certainly have been detected. For water vapour, the tests have so far been less delicate, and are not fully decisive—though the quantity present on either planet must be small. More delicate tests, with stronger lines, may soon be made on new red-sensitive plates.

There can be no reasonable doubt, on quite different evidence, that some small amount of water vapour is actually present in the atmosphere of Mars. Radiometric observations of the planet's heat show definitely that the surface rises to temperatures above 0° C. at noon every day in the Martian tropics, and at the pole at midsummer, though falling far below freezing at night. The polar caps must therefore really be composed of snow, and evaporate into water vapour, even if the pressure is so low that the ice turns directly into vapour without melting. The only plausible alternative suggestion—carbon dioxide—would volatilise at much lower temperatures than the actual polar caps do. But, judging from the amount of solar heat available to evaporate them, the polar caps must be very thin—probably only a few inches thick. The vapour resulting from the gradual sublimation would never attain any considerable density, and might easily fail of detection by the tests which have so far been practicable.

Identification of Carbon Dioxide

No such independent evidence is available for Venus; but Adams and Dunham, in 1932, discovered, in the infra-red region of its spectrum, three beautifully defined bands with heads at $\lambda 7820$, $\lambda 7883$ and $\lambda 8689$, and evidently of atmospheric origin. They had not then been observed elsewhere, but an immediate suggestion regarding their origin was obtained from the theory of band spectra—by that time well developed. The spacing of the individual lines in a band arises from the rotation of the molecule, and depends upon its moment of inertia. For the new planetary band, it showed that the otherwise unknown molecule involved must have a moment of inertia of 70.5×10^{-40} C.G.S. units. This agreed almost exactly with that of the molecule of carbon dioxide—already known from laboratory observations in the infra-red. All doubt regarding this identification was removed when Dunham, passing light through 40 m. of carbon dioxide at a pressure of 10 atmospheres, found that the strongest of the bands found in Venus was faintly absorbed. Recently, Adel and Slipher, using a path of 45 m. through gas at 47 atmospheres pressure, have found the bands considerably weaker than as they appear in the planet. They conclude that the amount of carbon dioxide above the visible surface of Venus is at least two mile-atmospheres—that is, equivalent to a layer two miles thick at standard atmospheric pressure and temperature. The whole amount above the planet's solid crust may be much greater. For comparison, it may be noted that the whole atmosphere of the earth amounts to five mile-atmospheres, and the oxygen in it to one and a quarter.

These bands do not show in the solar spectrum, even when the sun is setting. But there is very little carbon dioxide in the earth's atmosphere, and the whole amount in the path, even at sunset, amounts to only thirty feet under standard conditions.

The weak absorption in these bands, like that in the visible bands of water vapour, arises because they involve high harmonics of the fundamental vibration frequencies—in this case, the fifth.

Ammonia and Methane in the Major Planets

So far, we have had to do with bands of familiar and readily identified molecules, but the major planets have been much more puzzling.

Jupiter shows a conspicuous band in the orange, which was discovered visually by Huggins in the earliest days of spectroscopy, and fainter ones in the green. These appear more strongly in Saturn, but only in the spectrum of the ball of the planet, and not at all in that of the ring—which might be anticipated, since the ring consists of a multitude of tiny isolated satellites, and should be quite devoid of atmosphere. Uranus, though its light is faint, shows the same bands, much more strongly, and many others in addition. One of

these, which closely coincides with the *F* line of hydrogen (λ4861), led Huggins to conclude that the planet's atmosphere was rich in hydrogen

This interpretation, though quite permissible at the time, was erroneous, for the line is absorbed only by dissociated *atoms* of hydrogen, which will not be present except at very high temperatures

The bands cut out so much of the red and orange light that the whole disc of Uranus appears decidedly green—an unusual colour, noticed from the time of the planet's discovery

In Neptune's spectrum, the bands are of enormous strength, cutting out the red almost entirely and making the planet look still greener. They are hard to observe visually in so faint an object, and the full realisation of their intensity came only with the admirable photographs of V. M. Slipher, in 1907 In later years, and with modern plates, Slipher has extended his observations far into the red, finding bands of ever-increasing strength—up to λ10000 for Jupiter, where there is light enough to follow the spectrum farthest.

For more than sixty years after their first discovery, and twenty-five after Slipher's spectrograms, these bands presented one of the principal unsolved puzzles of spectroscopy—for no one had duplicated them in the laboratory. To be sure, one group, near λ7200, agrees fairly well with a band of water vapour, but the still stronger water-bands deeper in the red are absent, so that this must be a chance coincidence

When the radiometric measures of Coblentz and Lampland, and of Nicholson and Pettit, showed that the temperature of the visible surfaces of Jupiter and Saturn must be well below − 100° C, while Uranus and Neptune are doubtless colder, the range of possibilities was very much narrowed. But it was not until 1932 that a young and brilliant German physicist, Rupert Wildt, realised the solution of the problem

Other gases, like water vapour and carbon dioxide, have strong fundamental absorptions in the infra-red, and fainter harmonics in the more accessible part of the spectrum, which demand a long absorbing path in the laboratory to bring them out Utilising observations of this sort, Wildt showed that certain bands in the spectrum of Jupiter near λ6470 and λ7920 agreed with those of ammonia, and others, at λ6190, λ7260, and λ8860, with bands of methane The original comparison was not quite conclusive, for with the moderate dispersion then employed the planetary bands had not been adequately resolved into their component lines. This was soon accomplished by Dunham, who found so complete a coincidence of the accurately measured individual lines that both identifications were put beyond all question. For ammonia, more than sixty lines were found to agree, and for methane eighteen lines in part of one band Some expected band lines were naturally blended with solar lines; but not one of importance failed to appear.

From these comparisons, Dunham estimates that the quantity of ammonia gas above the visible surface of Jupiter is equivalent to a layer ten metres thick under standard conditions In Saturn it is less

The climax of the tale came in 1934, when Adel and Slipher announced that practically all the bands had been identified, and were due to methane The 45-m path, and the 40-atmosphere pressure, got enough of the gas into the way of the light to produce bands intermediate in intensity between those in Jupiter and in Saturn At this high pressure, the lines flowed together, and produced diffuse bands, but the agreement of these with the planetary bands was so complete as to be decisive

A further, and wholly conclusive, test could be added The fundamental frequencies of vibration of the methane molecule were already known, from observations in the infra-red For the higher harmonics of these vibrations, the frequencies are not exact multiples of the lowest, but nevertheless bear a simple numerical relation to them (as is well known in the case of other gases) Applying this test, the strongest bands (including Huggins's band in the orange, and the one coincident with the blue hydrogen line) were found to be harmonics, from the third to the eighth, of one of the fundamental frequencies, while another slower vibration was represented by all its harmonics from the eighth to the sixteenth The remaining bands were accounted for by combinations of these harmonics with other known frequencies, all of types consistent with the well-established rules which govern band spectra. Thirty-six bands in all have been identified. Many of these appear only in Uranus and Neptune, and have not yet been produced in the laboratory, but the harmonic relations just mentioned make their identification certain. The higher gaseous hydrocarbons, ethane, ethylene and acetylene, all have bands in places clear of disturbance by the methane; and all were looked for in vain. All the planetary bands of any importance are accounted for by methane alone—it is a clean sweep

From the published data, it appears that the amount of methane above the visible surface of Jupiter is of the order of one mile-atmosphere. There must be much more on Uranus, and especially on Neptune, but we cannot yet estimate its amount.

There is still plenty of work to do upon these bands; but mainly for the theoretical investigator. Adel calculates that the band at λ5430,

when fully resolved, should consist of eighteen different overlapping systems of many lines each Fortunately, the astrophysicist need not wait to draw his conclusions until this has been completely analysed.

Atmospheres in Relation to Planetary Masses

The results of observation can be summarised in a sentence. Large planets have atmospheres containing hydrogen compounds, middle-sized planets, atmospheres containing oxygen compounds; and small planets no atmospheres at all. The reason, in the last case, was found by Johnstone Stoney in 1897 It is simply that small bodies have not sufficient gravitative power to keep their atmospheres from diffusing away into the vacuum of interplanetary space. At the surface of any planet, there is a certain velocity of escape, depending only on its mass and radius A body projected from its surface, in whatever direction, with this or any higher velocity, will fly off in a parabolic or hyperbolic orbit and never return—unless, indeed, it meets with some obstacle or resistance on its outward way. For the moon this velocity is 2·4 km. per second; for the Earth, 11 2 km /sec, for Jupiter, 60 km /sec

Now the molecules of any gas are continually flying about in all directions, with average speeds which depend upon their weights At 0° C the average speed for a hydrogen molecule is 1·84 km /sec, for oxygen, 0 46 km./sec., for carbon dioxide, 0·39 km./sec. If an atmosphere of hydrogen could be put upon the moon, every molecule that was moving but a little faster than the average would fly off at once into space, unless it was thrown back by collision with another, and the atmosphere would diffuse away in a very short time With an escape velocity three times the average speed, enough fast-moving molecules would get away to reduce the atmosphere to half its original amount in a few weeks (according to Jeans). The rate of loss falls off very rapidly beyond this, so that, with an average velocity one fifth that of escape, the atmosphere would remain for hundreds of millions of years. The moon's surface reaches a temperature exceeding 100° C. during every rotation, and it follows that neither air nor water-vapour could permanently remain above its surface. If at any time in its past history, it has been really hot, like molten lava, it could have retained no trace of atmosphere.

For Mercury, the escape velocity is half as great again as for the moon; but the planet, being so near to the sun, is much hotter, and it, too, cannot retain an atmosphere. Mars, with an escape velocity of 5 km./sec., could not hold hydrogen; but should retain water-vapour—as it appears to have done—and all heavier gases. Venus and the earth, at their present temperatures, should retain even hydrogen, and the major planets would do so even if incandescent.

This reasoning explains the cases of Mercury and the moon, and leads to the important conclusion that all smaller bodies, such as the asteroids and satellites, must be wholly devoid of atmosphere—except perhaps bodies like Neptune's satellite, which is relatively massive and must be very cold. We cannot be sure about Pluto, for we know neither its size nor its mass; but it is probable that, at most, it may have a thin atmosphere, like Mars

The same principle was invoked, shortly after its discovery, to explain the great difference in mean density between the major and the terrestrial planets. The Moon, Mercury, Mars, Venus and the Earth all have densities between 3 3 and 5 5 times that of water The rest are almost certainly what we know the Earth to be, spheroids of rock, with cores of metallic iron of varying sizes For the major planets, the densities range from 1 6 for Neptune to 0 7 for Saturn Moulton suggested, about 1900, that they contained great quantities of light substances, which the smaller terrestrial planets had not been able to keep from diffusing away into space. This has been fully confirmed by later studies

From the ellipticity of a planet and the changes in its satellites' orbits caused by the attraction of its equatorial bulge, information may be obtained regarding the degree to which the density increases toward its centre. Applying this to Jupiter and Saturn, Jeffreys concludes that they contain cores of rock and metal, like the inner planets, surrounded by vast shells of ice—frozen oceans thousands of miles deep—and above this, again, atmospheres of great extent Throughout most of the atmospheres, the pressure must be so great that the gas is reduced to a density as great as it would have if liquefied, or even solidified, by cooling. Indeed, Wildt believes that the enormous pressure would actually solidify even the 'permanent' gases.

Now this outer layer is of low density—less than 0 78 for Jupiter and 0 41 for Saturn—according to Wildt's calculations This excludes all but a few possible constituents. Frozen oxygen has a density of 1·45, nitrogen 1 02, ammonia 0·82. Only hydrocarbons (methane 0·42, ethane 0·55), helium (0·19) and hydrogen (0·08) come within the limits even for Jupiter. We can therefore conclude, from considerations of density alone, that the outer parts of Jupiter probably, and of Saturn certainly, contain great quantities of free hydrogen or helium. Uranus and Neptune are similar to Jupiter.

Evolution of Atmospheres

It is generally believed that the planets have been produced, in some way or other, from matter ejected or removed from the sun No really satisfactory theory of the process of formation has yet been devised, but no other hypothesis has yet done better, and the isolation of the sun and planets in space makes a common origin highly probable

Now we know the composition of the sun—at least of its outer layers—much better than we do that of the planets Quantitative spectroscopic analysis, though still beset with difficulties, has advanced far enough to show that most of the sun's outer layers is composed of hydrogen, next come helium, oxygen and carbon, followed by nitrogen, then silicon and the metals A mass of matter removed from the sun and allowed to cool without serious loss would therefore closely resemble the major planets If small enough to lose all its atmosphere, it would be like the moon or the asteroids—though there are difficulties in seeing how such small masses could have escaped diffusing away altogether before the more refractory constituents solidified

The history of a body of intermediate mass is more interesting Hydrogen and helium would be lost while the body was still very hot. So would most of the other light gases such as neon and nitrogen (which at the temperature even of the sun's surface is dissociated into atoms) Free oxygen, too, would escape, but a good deal might be retained in combination with silicon and the metals As the gaseous mass cooled, by expansion and radiation, drops of molten metal and lava would form within it, as Jeffreys suggests, and fall toward the centre, building up a molten core After the first turbulence was over, there would remain a molten planet surrounded by an atmosphere containing heavy inert gases such as argon, perhaps some carbon dioxide, and as much of the nitrogen and neon as had failed to escape Menzel and I, a few years ago, noticed that neon, while apparently fully as abundant in the stars and nebulæ, is but 1/500 as abundant in the earth's atmosphere, while nitrogen, which is cosmically an abundant element, showing strong spectral lines, forms but a very small portion of the earth's mass It appears, therefore, that a mass of the earth's magnitude must have lost almost, though not quite, the whole of its primitive atmosphere

Still following Jeffreys, it appears that, as the molten earth cooled, the two thousand mile deep sea of lava solidified first at the bottom (where the melting point was greatly raised by pressure) and so gradually to the surface During this process, great quantities of gases, mainly water vapour, must have been evolved from the solidifying magma and escaped to the surface, forming a new atmosphere which now would not escape, since the surface was cooler With solidification would come rapid superficial cooling and an ocean would bathe the rocky crust, leaving an atmosphere of moderate extent Carbon dioxide—evolved from the magma, and perhaps partly primitive—would be a major constituent, along with nitrogen, argon, neon and other minor left-overs The presence of free oxygen seems very unlikely, for practically all volcanic rocks and gases are unsaturated with respect to this element—the former containing much ferrous iron, and the latter being often actually combustible when they meet the air

The present rich supply of oxygen appears to be a by-product of terrestrial life (This suggestion is more than a century old.) The earth, indeed, may be regarded as an intensively vegetated planet, from the atmosphere of which the greedy plants extract the remaining residue of carbon dioxide so rapidly that if it were not returned to the air by combustion, respiration and decay, the whole supply would be exhausted in a decade or so Oxygen removed from the atmosphere by these processes is speedily returned by plants, but there is another process of slow depletion which is irreversible During rock-weathering, about half the ferrous iron of the rocks is oxidised to the ferric state Goldschmidt (from whose admirable geochemical papers the present discussion is borrowed) concludes that the amount of 'fossil' oxygen thus buried in the sedimentary rocks is at least as great as that now present in the atmosphere, and may be twice as great An amount of carbonaceous or other organically reduced material equivalent to both the free and the fossil oxygen must also be in the sediments—which is not unreasonable Given time enough, this inexorable process of rock-decay might exhaust the remaining oxygen of our atmosphere, and put an end to all that breathes But this danger is indefinitely remote—a billion years away anyhow, since life has lasted that long, and only half the oxygen has been used up, and probably much longer, for volcanic gases are still carrying 'juvenile' carbon dioxide into the air that has never been there before

It is of no small interest, however, to look at Mars and see there what looks very like the end of this process The reddish colour of the planet—unique among the heavenly bodies—is just what might be expected, and indeed is almost inevitable in a surface stained with ferric compounds (The unoxidised rocks of the moon are grey or, at most, brownish) Wildt suggests that, in the thin atmosphere of Mars, the ozonised layer produced

by the action of ultra-violet light at the top of the atmosphere should be near the surface—not high up as it is here—and that oxidation processes at the planet's surface might thus be accelerated

It would be premature, however, to conclude that Mars must be a lifeless planet The depletion of oxygen would be very slow, and plant-life would probably adjust itself—as it has done on earth in response to far more rapid climatic changes Whether animal life, if ever present, could have survived, is speculation A race of no more intelligence and engineering skill than our own could presumably meet the situation and survive in diminished numbers breathing electrolytic oxygen—provided that it paid any attention to changes so slow as to be imperceptible in a thousand generations!

While Mars resembles the final stage of our suggested process, Venus seems to be at the beginning, and much like what a lifeless earth would be We do not know how life began here, but conditions may well have been much less favourable on Venus Wildt concludes that the powerful 'blanketing' effect of the atmospheric carbon dioxide, combined with the stronger solar radiation, may raise the temperature at the planet's actual surface to 100° C or higher—in which case the failure of life to develop is not surprising The real puzzle is the apparent absence of water on the surface of Venus The planet is almost a twin of the earth in size, mass, density and so on, and one might have expected an ocean of comparable volume Wildt suggests that all the water has gone into hydrated minerals, but how this could happen unless there was much less there originally than on earth is hard to understand

Course of Chemical Changes

For the major planets, we have to consider the course of events in a cooling mass containing an excess of the lighter elements and especially of hydrogen The condensation of the refractory constituents should take place much as for a smaller body The principal constituents of the rocks, however—potassium, sodium, magnesium and calcium, and likewise silicon—are not reduced from their oxides by hydrogen, and would form rocks not unlike those of the earth But at high temperatures the oxides of iron are reduced by hydrogen My colleague, Prof H S Taylor, remarks that the drops of molten lava falling through a hydrogen atmosphere reproduce fairly closely the conditions of a blast furnace We may conclude then that most of the iron would go into the core and less into the rocky shell

After the core solidifies, the remainder of the mass will remain fluid over a wide range of temperature. Its principal elementary constituents will be hydrogen, helium, oxygen, carbon and nitrogen, with smaller quantities of the other inert gases, sulphur and the halogens

The principal reactions which occur in such a gaseous medium at different temperatures and pressures have been carefully studied, for, in addition to their theoretical interest, they are of great practical importance in chemical industry

When oxygen, carbon and hydrogen are considered, the main reaction is

$$CO_2 + 4H_2 \rightleftharpoons CH_4 + 2H_2O$$

The formation of methane is accompanied by diminution of volume hence it will be favoured by high pressure High temperature works the other way from the free-energy data it appears that, at 1000° C and atmospheric pressure, the equilibrium inclines to the side of carbon dioxide, even in the presence of a large excess of hydrogen Below 300° C practically all the carbon should go into methane at about 600° the amounts of the two gases should be comparable

With hydrogen and higher hydrocarbons, the tendency of the reaction is always toward methane at low temperatures With saturated hydrocarbons, this involves no change of volume and should not be affected by pressure Formation of methane from unsaturated hydrocarbons should be favoured by high pressure The exclusive presence of methane in the planets' atmosphere might thus have been predicted

The formation of ammonia from its elements, in accordance with the equation

$$N_2 + 3H_2 \rightleftharpoons 2NH_3$$

liberates less energy With excess of hydrogen, and at atmospheric pressure, the amounts of nitrogen and ammonia should be equal between 200° and 300° C, ammonia should predominate at lower temperatures, and at higher pressures The oxides of nitrogen are endothermic, and so would tend to dissociate, rather than to form

We may now form a definite picture of the successive reactions which will occur in the atmosphere of a cooling major planet At temperatures of about 1000°, the predominant hydrogen will be mixed with steam, free nitrogen and carbon dioxide—the carbon monoxide which occurs in stellar atmospheres having long ago been completely oxidised. With falling temperature, the carbon dioxide will be converted into methane before the water reaches its critical temperature and begins to condense After most of it has been precipitated, the nitrogen will go over into ammonia These reactions, however, will run their course at these relatively low temperatures only with appropriate activation For the formation of methane, an excellent catalyst is available in the partially reduced oxides of iron which should

be present on the rocky surface exposed to hot hydrogen These would be equally good for the ammonia, but they may be at the bottom of the sea by the time the proper temperature is reached An adequate activation, however, would be furnished by electrical discharges—and, if terrestrial thunderstorms are any guide, these should be abundant so long as vapours arising from the hot ocean are being condensed. When the temperature has fallen to that which the earth at present enjoys, there will be an extensive atmosphere of hydrogen, mixed with the simple hydrides—methane, ammonia and water vapour—along with any inert gases which may all along have been present, but with little or no free nitrogen or carbon dioxide Below this will be an ocean—perhaps very deep, strongly alkaline with ammonia, and incidentally containing in solution any compounds of sulphur and the halogens which may originally have been present The conditions in such an alkaline ocean —its action on the rocky bed, the compounds which it will hold in solution, and the deposits which it may form—would be of great interest, but are outside our present scope

With further cooling the water will freeze, but at a temperature below 0° C depending on the percentage of ammonia With one part of the latter to two of water, the freezing point would drop to −100° C, but it is doubtful if there is enough ammonia for this The major planets—even Jupiter—are still colder, and the water must be thoroughly frozen out of their atmospheres, leaving only ammonia and methane The ammonia, indeed, must be at the point of precipitation Dunham has obtained in this way a minimum temperature for Jupiter's visible surface The ten metres of ammonia above the surface, under the planet's surface gravity, should exert a pressure of 1 5 mm. (on the familiar laboratory scale). The vapour tension of the solid (below the triple point) has this value at −107° C. At a lower temperature, the observed quantity of ammonia could not exist in the atmosphere—it would partially condense itself by its own weight

If the atmosphere consists mainly of hydrogen this limit may be lower, for the mean molecular weight is diminished, and the partial pressure of the ammonia in the same proportion. With a large excess of hydrogen, the pressure may be reduced to one sixth of the previous value and the limiting temperature to −120° C.

The direct radiometric observations of Jupiter indicate a temperature of about −135°, but this determination is complicated by large and rather uncertain corrections for the absorption of infra-red radiation in the atmospheres of the earth and the planet, so that the agreement is about as good as could be expected It is, therefore, very probable that the clouds which form Jupiter's surface are composed of minute crystals of frozen ammonia. A perfectly absorbing and radiating planet, at Jupiter's distance and heated exclusively by the sun, would have a mean temperature of −151° C The excess in the actual temperature may be attributed partly to the fact that we observe the sunlit (and warmer) side, partly to the 'greenhouse' effect of the atmosphere, which lets in the short-wave radiation from the sun much more easily than it lets the long-waves emitted from the planet's surface out again; and partly, perhaps, to some residual internal heat in the planet The existence of the latter is made probable by the rapid changes in the cloud-forms, which often suggest the ascent of new material from below The variety of colours upon the surface, which range from clear white through pinks and browns almost to black, remain unexplained.

On Saturn, where the ammonia bands are fainter than on Jupiter and the surface gravity is less than half as great, the limiting temperature may be 10° or 15° lower The radiometric observations indicate about the same difference

Uranus and Neptune, being farther from the sun, should be still colder The ammonia should be frozen out of their atmospheres, leaving them clear to a greater depth, which may explain the extraordinary strength of the methane bands in their spectra. The methane itself must be nearly ready to condense on Neptune, despite its very low boiling point Assuming, roughly, that Neptune has six mile-atmospheres of methane above its surface, the pressure, due to this alone, would be about 500 mm and the limiting temperature −165° C A large excess of hydrogen might reduce this to −183°. Solar radiation alone would maintain a mean temperature near −220°. Whether the difference arises from the powerful 'greenhouse' effect of the methane itself, or from internal heat, cannot yet be determined It may be, however, that if the methane could once be frozen out of Neptune's atmosphere, the surface temperature would fall so much that it would stay frozen, and leave the planet with an atmosphere which, apart from the inevitable Rayleigh scattering, exerted no influence upon visible light

The problem of planetary atmospheres, so perplexing a few years ago, is now far advanced toward its solution. Towards its interpretation many sciences have contributed—astronomy, physics, chemistry, geology, biology and technology. No one of them alone could have resolved the difficulties. It may, therefore, be appropriate that the attention of so general a scientific gathering may have been invited for a while to it: for it truly illustrates the old motto "In union there is Strength".

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD., ST. ALBANS

organisation of an International Air Police are insignificant compared with the difficulty of finding any practical defence scheme which has the remotest chance of becoming effective.

Civil Aviation Wireless Plans

THE plans which have been approved for the establishment of new civil aviation wireless stations in Great Britain will provide for the establishment of a chain of wireless stations throughout the country, so as to afford full facilities for direction-finding, for communication with aircraft, and between airports Three new stations came into operation last year, at Hull, Portsmouth and Nowtownards (Belfast) A further six are under construction and will be placed at suitable sites during 1935 These sites are being chosen with the object of providing a direction-finding network covering the new internal routes, as well as to serve the needs of individual aerodromes The equipment will be mounted on vehicles capable of being easily moved from place to place A limited number of permanent stations of higher power are also to be erected. The first of these will be established at Heston Airport to relieve the growing congestion at Croydon It is also the intention of the local authorities to build a station in the Channel Isles. Three new permanent direction-finding stations, in addition to those already existing at the same points, are being brought into operation at an early date on the Continental airway, at Pulham, Lympne and Croydon. The radio-beacon at Croydon is now being modified to operate on the aural principle, thus making it available for any aircraft fitted with an ordinary receiver On the completion of this reorganisation there will be available for the assistance of aircraft flying on the Continental routes seven direction finders, seven transmitters and one radio beacon

A New Depth-Sounding Recorder

THERE are several types of marine devices for finding the depth of the sea by means of 'echo-sounding'. One or two of these not only give isolated indications of the depth of the sea, but also provide a more or less continuous record of the sea bed The British Admiralty uses a low-frequency type of oscillation which is reflected from the bottom of the sea, the time of going and returning being marked on an electro-chemical recorder A high-frequency system using the vibrations of a quartz piezo-electric oscillator, devised by Langevin and Chilowsky, has been developed commercially in Great Britain by the Marconi Sounding Device Co An entirely new type of high-frequency echo depth recorder which possesses important advantages was described to the Institution of Electrical Engineers on January 2 by A. B. Wood, F. B. Smith and J. A. McGeachy This device can give a continuous record of the depth of water beneath a survey motor-boat of about 2 ft. draught travelling at full speed. According to the specification, it had to measure a depth ranging up to 200 feet with a maximum inaccuracy of about one foot. The method employed gives a practical application of the phenomenon of magneto striction Two oscillators of this type—a transmitter and a receiver—are mounted in water filled tanks and fitted in a chosen position in the motor-boat The transmitter is excited into resonant vibration at regular intervals of time depending on the range of depth to be recorded. A short train of high-frequency sound waves is directed vertically downwards to the sea-bed and reflected back to the receiver The induced currents are amplified, rectified and passed through a recorder During the time the sound impulse is travelling from the transmitter to the receiver via the sea bed, the recording point has travelled a corresponding distance on the paper The time for the going and return journey is thus found The method has been proved satisfactory for depths exceeding 400 fathoms.

Vital Statistics for 1933

LAST week (p 181) we printed a note referring to the provisional figures of the vital statistics for 1934 The Registrar General's Statistical Review for 1933, Tables (Part II, Civil) is now available (London: H M. Stationery Office 2s 6d) It includes a table showing the populations of England and Wales, Scotland and Ireland as enumerated at each Census from 1821 until 1931, and as estimated for each year 1894–1933 inclusive The population of England and Wales is now estimated as 40,350,000 at the middle of 1933, the 1931 Census figure being 39,952,377 The births registered during 1933 numbered 580,413 a decrease of 33,559 on the previous year's figure The consequent birth rate of 14·4 per 1,000 population is the lowest recorded for England and Wales, being 0 9 below that for 1932 the previous lowest, and 1·4 below that for 1931. The only countries showing a lower rate in 1933 were Sweden (13·7) and Austria (14 3) The proportion of the sexes in the births registered during the year was 1,046 males to 1,000 females

Association of American Geographers

THE thirty-first annual meeting of the Association of American Geographers, with Dr Wallace W Atwood presiding, was held at the University of Pennsylvania, Philadelphia, on December 27–29 Forty-nine papers were presented, including six in the field of geomorphology, five in climatology, and two in cartography The remaining papers ranged the whole field of geography, and included discussions of particular problems or areas A half-day session was devoted to a conference on regional geography. As retiring president, Dr Atwood addressed the Association on "The Increasing Significance of Geographic Conditions in the Growth of Nation States". For the forthcoming year the following officers were elected: *President*, Prof. Charles C Colby, University of Chicago; *Vice-President*, Col C. H. Birdseye, U.S. Geological Survey; *Treasurer*, Prof. John E. Orchard, Columbia University; *Councillor*, Prof. Kirk Bryan, Harvard University, *Secretary*, Prof. Frank E. Williams, University of Pennsylvania.

Congress on Dog Breeding

An event of considerable interest to geneticists, psychologists, and especially to dog fanciers, is to take place at Frankfort on Main on April 22–25, when the Fédération Cynologique Internationale (F C I) is to hold its third congress, which will be followed (April 26–28) by a dog show, open to all the world, and providing classes for all the known breeds Discussion at the congress will deal mainly with the inheritance of the physical and mental characters of the dog, and papers will be presented by Prof Henseler, of the Institüt fur Tierzucht und Zuchtungsbiologie in Munich, Prof Pirocci, of Milan, Dr Méry, of Paris, and Major Most, of Berlin Particulars concerning membership and programmes may be obtained from Fr Bazille, Rotenwaldstr 83a, Stuttgart-W

Holly Lodge Farm

According to *The Times* of February 6 the Conservative Parliamentary Agricultural Committee on February 5 unanimously adopted the following resolution "That in view of the authoritative opinions on the educational and research value of the Holly Lodge and Crown Farms, Walton-on-Thames, especially in view of the Government's policy for the greater home production of fruit, vegetables, and flowers to replace foreign imports, this Committee expresses the earnest hope that these farms will not be destroyed under the reservoir scheme of the Metropolitan Water Board"

Announcements

Prof A C Seward professor of botany in the University of Cambridge, has been elected president of the South Eastern Union of Scientific Societies in succession to Prof H L Hawkins The annual congress will be held at Bournemouth on June 26 29

Prof A L Goodhart, professor of jurisprudence, Oxford, Sir Walter Moberly, chairman of the University Grants Committee, and Prof. G P Thomson, professor of physics, Imperial College of Science, have been elected members of the Athenæum Club under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public service

On February 18 in the Lecture Hall of Manson House, Portland Place, Col MacArthur, late R A M C., will be presented with the Chadwick Gold Medal and Prize of £100 which, under the scheme of the trust, may be awarded once in five years to the medical officer of the Navy, Army or Air Force who has most distinguished himself during that period in promoting the health of the men of the Service to which he belongs.

Sir Peter Chalmers Mitchell, who has been a member of Council since 1900 and secretary since 1903 of the Zoological Society of London, retires from that office on April 29, 1935 It is therefore proposed to present to the Society a portrait in oils of Sir Peter, by Mr William Nicholson Fellows and friends of the Society are invited to send contributions to the Portrait Secretary, c/o F W Bond, Zoological Society of London, Regent's Park, N W 8.

At the meeting of the Industrial Research Council, Irish Free State, on February 2, it was announced that Mr Eugene Boyle has been appointed chemical engineer for research on waxes under Prof J Reilly in University College, Cork

At the twenty ninth annual meeting of the Botanical Society of America on December 27–29 in Pittsburgh, Pennsylvania, the following elections were made *President*, Dr Aven Nelson, University of Wyoming, *Vice-President*, Dr K M Wiegand, Cornell University, *Corresponding Members*, Sir David Prain, lately director of the Royal Botanic Gardens, Kew, Prof G Haberlandt, emeritus professor of botany, University of Berlin, Prof Alvar Palmgren, professor of botany, University of Helsingfors

The first (January) issue of the *Traveller*, the quarterly journal of the University Travel Guild, contains short accounts of excursions of scientific, historical, architectural, musical, etc., interest which are being arranged by the Guild in 1935 Tours of scientific interest include "Palestine of the Bible", under the leadership of Dr E W G Masterman; "Dalmatia a Botanical Tour", under the leadership of Dr W. B. Turrill, and Roman France Copies of the *Traveller* (price 4*d*, or including postage 6*d*.) and further particulars of the University Travel Guild can be obtained from its offices, 25 Cockspur Street, London, S W 1

Applications are invited for the following appointments, on or before the dates mentioned —An inspector of mine beacons in the Department of Mines, Southern Rhodesia—The Official Secretary, Office of the High Commissioner for Southern Rhodesia, Crown House, Aldwych, London, W.C.2 (Feb 16) A lecturer in botany and physics at the Cheltenham Technical College—The Secretary (Feb 18) A technical officer in the Admiralty Technical Pool—The Secretary to the Admiralty (C E Branch), Whitehall, London, S W 1 (Feb. 18) A lecturer in hygiene and public health in the Charing Cross Hospital Medical School, 62 Chandos Street, W C 2 —The Dean (Feb. 20). An assistant inspector of guns (metallurgy) in the Metal and Steel Factory, Ishapore (Indian Ordnance Department)—The Secretary, Military Department, India Office, London, S W 1 (Feb. 20). A general manager and engineer in the Electricity Department of the Metropolitan Borough of Battersea—The Town Clerk, Battersea Town Hall, London, S.W.11. An assistant chemist, a junior chemist, and a biologist on the staff of the Research Association of British Flour Millers—The Director of Research, Old London Road, St. Albans.

Letters to the Editor

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 235

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Light of the Night Sky

I HAVE succeeded in exciting the auroral green line under conditions which indicate that it must have been produced in a manner similar to that in the light of the night sky In order to describe my experiments properly, it is necessary first to recall the excitation of the green line in active nitrogen[1] In that experiment it was possible for the first time to produce the green line under conditions which give some clue to its production in both the aurora and the night sky, since there are metastable nitrogen molecules in active nitrogen, and one would certainly expect metastable nitrogen to play an important rôle in the upper atmosphere My recent discovery of a new modification of active nitrogen[2], the afterglow of which was a very faithful reproduction of that part of the auroral spectrum which is due to nitrogen, added an argument for the hypothesis that the green line is excited by metastable nitrogen molecules

Second-positive bands of N_2 5577

FIG 1

In the new experiments, a very small amount of oxygen, about one per cent, was introduced into the tube in which the new afterglow was discovered The discharge, and not the afterglow, was photographed with the current in the tube interrupted periodically. At first the interruptions were spaced so that the current was on long enough to allow the current in the bulb of the tube to reach its full value The discharge in the bulb was green-white, and the green line was absent under these conditions When the current was interrupted more rapidly, the discharge in the bulb was much weaker and its colour was red Certain very profound changes took place in the spectrum of the discharge in the bulb The most important one was the presence of the green line, with an intensity which resembles very closely its intensity in auroral and night sky spectra, and also unaccompanied by other oxygen lines (Fig. 1) The first-negative bands of N_2+, which are strong in the discharge when the current is allowed to reach its full strength, were almost completely missing The second-positive bands of N_2 were present The recently discovered Vegard-Kaplan intercombination bands of nitrogen were excited, but in the rapidly interrupted discharge the high wave-length members of the system increased greatly in intensity relative to the other N_2 bands, as compared with their intensity in the slowly interrupted discharge The Goldstein bands, to which attention was directed recently by Hamada[3] in connexion with the light of the night sky, were missing in the rapidly interrupted discharge, although they were present in the slowly interrupted one.

The most important results of these experiments are the excitation of the green line, the increased intensity of the long wave length members of the Vegard-Kaplan system and the absence of the Goldstein bands The first two indicate that the members of the Vegard Kaplan system probably occur in the night sky, and the absence of the Goldstein bands casts some doubt on Hamada's identification of the X_1 and X_2 lines as members of that system The absence of the first negative bands is in good agreement with their very feeble excitation in the light of the night sky Longer exposures have been started in an attempt to observe the red oxygen lines which usually accompany the green auroral line and also to observe the visible members of the Vegard-Kaplan system It is believed that we have a very good reproduction of the light of the night sky in these experiments and hence a means for identifying the radiations which are actually observed in the night sky

With regard to the identification of the two X_1 and X_2 lines, 4416 and 4168, it may be said that Dufay observed two lines in the night sky at 4422 and 4171 which are probably identical with Rayleigh's line. The Vegard-Kaplan bands (2,14) and (3,14) lie at 4423 and 4170 respectively. Dufay also observed lines at 4268, 4044, 3984 and 3951. Vegard-Kaplan bands nearest to these lines lie at 4271, 4043, 3978 and 3947 These agreements, together with the above mentioned experimental results, indicate that we have definitely identified some of the radiation in the night sky

Zero Point Energy and Physical Properties of H_2O and D_2O

THE marked differences between the physical properties of H_2O and D_2O (and of all polar compounds of H and D) cannot be due to intramolecular differences, which are far too small, but must be connected with differences of effective intermolecular forces It is possible to account for these differences in a quantitative way by taking into consideration the differences in the frequency of angular vibration or *libration* of a molecule in the field of its neighbours The mean frequency in ice can be calculated from the model of the water molecule already put forward[1] The frequency found, $\nu_B = 14 \cdot 3 \times 10^{12}$ sec.$^{-1}$, is large enough to have a zero point energy of 17 per cent of the total energy of ice. As in such a libration only the hydrogens

are effectively in motion, it is decreased by the factor $\sqrt{2}$ on substituting D for H. Apart from less important changes due to symmetry conditions and the differences in the nuclear spins, this change of frequency accounts for the greater part of the difference of energy content and specific heats of H_2O and D_2O. Thus the differences of the heats of evaporation of D_2O and H_2O ices at the melting points is calculated 0.35, as against the observed value[2] of 0.32 k. cal. per mol. This may be regarded as the best check of the essential correctness of the theory. The difference of the specific heats of ice are calculated as 0.7 and observed[3] c. 1 cal. per mol. degree.

In water ν_B must clearly have a lower value than in ice, from which it follows that the molecular latent heat of fusion of D_2O ice must be greater than for H_2O ice. This is also in agreement with experiment. Besides the librations, the water molecules undergo normal vibrations but of lower frequency $\nu_A = 5 \times 10^{12}$ sec^{-1} and far less affected by the substitution of D for H. Using the frequencies ν_A and ν_B it is possible to calculate the specific heat of ice. At the melting point it is 9.35 as against 8.85 cal. per mol. degree observed.

Wave-length shifts corresponding to $\nu_A = 4.6-6.7$, $\nu_B = 15 \times 10^{11}$ sec^{-1} have been observed in the Raman spectra of water by Magat[4] in reasonable agreement with the values derived by calculation from the model.

Corresponding energy differences may be expected to occur in the solid or liquid state of all hydrogen compounds which possess polar properties. The difference in the energies of H and D hydroxyle will depend on the temperature and the vibration frequency and hence on the field in which the hydroxy group is placed. The stronger the binding the greater the difference. Hence this difference will increase as we pass from the amphoteric hydroxyl bond to that of the alcohols and from them to the hydrogen bond of acids. Similarly, in the hydration of ions the difference will depend on the relative hydration energy and will be accordingly greater for strongly polarising ions. A study of the physical properties of D compounds cannot fail to throw light on the structure of the corresponding H compound and may prove a powerful method for discovering the principles of structure of molecular solids and liquids.

The Pair Bond Theory of Valency

THE method of molecular orbitals (Hund, Mulliken, Lennard-Jones), which is especially designed for the description of a completed molecule can be worked out in high approximations only in the simplest cases. In more complicated ones, it is therefore not able to describe the process of dissociation, which is clearly the essential requirement of a theory of valency. Accordingly it is necessary to resort to the correlation table which, however, gives only qualitative results, and no information regarding the quantitative loss or gain of energy. An additional assumption is therefore necessary, and this is found in the hypothesis that bonding power is always ascribed to the lowest one of a group of terms, resulting from the same atomic term by splitting due to the removal of a degeneracy. The wave-function of this term in the case of one electron linking the two cores A and B is

$$a\psi_A + b\psi_B \qquad (1)$$

and

$$\{a\psi_A(1) + b\psi_B(1)\}\{a\psi_A(2) + b\psi_B(2)\} \qquad (2)$$

in the case of two electrons. The wave-function (1) shows that a linkage can be brought about by a single electron only if the atomic fields in question are either equal ($a = b$) or almost equal ($a \approx b$), and this is why the method of molecular orbitals has recently been interpreted as leading to a single-electron bond theory. When the degeneracy of the fields gradually disappears, function (1) becomes, however, simply ψ_A or ψ_B, whichever is lower, showing that the bonding power ceases when the difference between the eigen-values of ψ_A and ψ_B is no longer negligible.

In our opinion, therefore, the degeneracy of (1) is not sufficient to be used as a foundation of a theory of valency, because the condition of approximate degeneracy is not satisfied in most practical cases, for example, in CO for the two p electrons introduced first into the field composed of C^{4+} and O^{4+}. Even in the case of exactly equal cores (except protons) the degeneracy is apparently too weak to bring about an actual chemical union by overcoming the repulsion of the cores (existence of Li_2, but non-existence of Li_2^+, etc.). It does not seem possible to reduce, as viewpoint (1) does, the linkage to a phenomenon of non-promotion of the single electron and to consider the interaction of several electrons on the same orbital as more or less negligible.

The interaction of the electrons, however, leads us to wave-functions of the type (2) with pairs of electrons on the same molecular orbital. The degeneracy due to the equality of the electrons is always rigorous and remains so, even if the degeneracy of the fields disappears completely ($a \gg b$ or $b \gg a$), that is, when the molecular orbital gradually changes into an atomic orbital, or in other words, the bond changes from covalency to electrovalency. This view, that the effect of degeneracy of the electrons predominates over the effect of degeneracy of the nuclear fields, leads to an interpretation of the orbital method as a pair bond theory of valency, without resorting to strict localisation of the bonds. It is our intention to show that this can be developed in detail.

Mathematically this second view is fully equivalent to the first, and it does not require the additional assumption of the preservation of approximate degeneracy for unequal fields. As either interpretation is based on a hypothesis, a decision between them is possible only by comparing their consequences with the experimental evidence, and the spectroscopical data on the dissociation of molecules, especially such as NO, BeO, CaF, etc., and CO_2 appears to be in better agreement with a pair bond theory of valency. A critical analysis of chemical

data, which in the light of this view has already been described[1], indicates that the experimental evidence is in better agreement with a uniform pair bond theory than with a single-electron bond theory of valency. A full report will be given elsewhere

Reafforestation of Forest Trees in Great Britain

SEVERAL letters and articles have recently appeared in the public Press directing attention to the necessity for the reafforestation of the hardwood trees of Great Britain

The Forestry Commission appointed shortly after the War for the purpose of replacing the losses resulting from the excessive war demand for home grown timber, has now had about fifteen years of steady work. The Commissioners were empowered to purchase land, and plant woodlands throughout the country; but their efforts have been confined mostly to the planting of softwoods, and with the exception of some limited areas there has been little or no planting of hardwood trees.

It is not generally realised that for quite a considerable time before the War, and during the years which have passed since, vast quantities of trees of oak, and ash, beech, walnut, etc. have been hewn down and gone into consumption. The destruction has proceeded on a scale far beyond anything which occurred during the previous hundred years, and now gradually every tree which is realisable has to come down, including every kind which possesses a monetary value, whether of mature growth or wholly immature. The tragic condition is particularly noticeable throughout Sussex, a county which was formerly one of our most beautifully wooded and richest in hardwoods.

Anyone who has travelled over long distances in India, America, and other parts of the earth, has seen areas which thoughtless men have denuded of all trees and are now barren wastes We are bringing about the same condition in England, and Sussex is by no means the only county which has suffered. As a writer has said: "Wherever man has settled the forests disappear. Up till now the march of civilisation has everywhere proclaimed the destruction of trees over the wide surface of the globe"

In 1925 I read a paper on this subject at the meeting of the British Association at Southampton, and again each year excepting one at the subsequent meetings until that in London in 1931; but the public is still quite unaware of the true state of affairs It is not realised that the once beautifully timbered parks and woodlands throughout the country are being completely wiped out.

Great Britain has been famous all over the world for the beauty and wealth of her woodlands, and because of the planting done by our landowners we were able before the War to boast of a fully sufficient reserve of valuable timber. The "march of civilisation" has overtaken us, and unless something is done there will be no escape from a deplorable result. The Irish Free State has handled this situation, and under the Forestry Act of 1928 made very stringent orders for the protection of its woodlands Application has to be made to the Department of Lands, Forestry Division, Dublin, and permits must be obtained by "*any* person who wishes to fell *any* tree on his holding", and licences may contain stipulations for replacement In England, Scotland and Wales, thousands of hardwood trees have been cut down and practically nothing planted; in southern Europe for every tree that is allowed to be felled hundreds are planted There must surely be something seriously wrong with us if we allow this state of affairs to continue

Interpretation of Animal Behaviour

IN a recent article on the "Interpretation of Animal Behaviour"[1] the view was advanced that a preoccupation with teleological explanations was necessarily somewhat unscientific and philosophical

Since the future development of psychology—and probably of biology—will depend largely on whether men of science agree to recognise the validity of purposive concepts or decide to consider them as being inadmissible, the question is of great importance Already, the nature and content of the problems investigated depend largely on what the investigators concerned think on this point

It is generally agreed, of course, that science necessarily operates in a world of objective fact and that it must be deterministic But it is unwise to assume that vitalistic theories or teleological interpretations are less scientific and deterministic, or more metaphysical, than are mechanical theories using efficient causation After all, the *facts* alone can be considered objective and *all* modes of interpretation or of analysis of them are, in a sense, subjective.

Again, the doctrines of efficient and of final causation are both philosophical in so far as they are merely principles of explanation not themselves contained in the facts studied Nor can it be maintained that preoccupation with teleology is necessarily unscientific In fact, the principal claim of the vitalist school is that the category of final causation is a legitimate weapon of *scientific* analysis, capable of being applied rigidly to particular problems It is difficult to understand why unfortunate teleologists should necessarily be relegated to the same scrap-heap as the universally despised metaphysicians!

Both the believers in efficient causation and the teleologists agree on one point: the present moment is not understandable in isolation Mechanists insist that the past is immanent in the present, teleologists insist that the future is equally immanent in the present. Clearly both are justified in their beliefs, but why should the latter alone be condemned as unscientific anthropomorphs?

If I may paraphrase Prof. A N. Whitehead, is it not true to say that those psychologists who are animated by the purpose of showing that neither they themselves nor the animals have purposes, form an interesting subject for psychological investigation?

J. A. LAUWERYS.

Institute of Education,
Southampton Row,
London, W.C 1.
Jan. 16.

[1] NATURE, 134, 995, Dec. 29, 1934

I AM afraid I neither realise the basis nor appreciate the strength of Mr. Lauwerys' clearly implied prophecy that fruitful developments of biology and psychology—by which I trust he means the study of behaviour, since that is the matter under discussion—depend largely on the acceptance of teleological ideas in general, and the concept of purpose in particular. The issues as they are stated are unfortunately vague, and difficult to discuss in a short space, but if prophecies in these matters are of any value, it seems to me that the futures of these subjects depend only upon the further recognition of sensible problems, capable of investigation, within the fields of objective fact to which they refer The criterion of objective fact, from the point of view of science, is that it constitutes a datum that is public in the sense defined by Hogben, and is capable of expression without fear of ambiguity.

The methods by which facts such as these may be analysed can be many and varied, provided they conform to the demands of proper scientific procedure Since it is perfectly legitimate to regard 'explaining' in science as being synonymous with generalising and hypothesising, it seems to me idle to contend that in science 'interpretations' and 'explanations' are any more subjective than the primary data to which they relate In this connexion it is well to remember that both opponents and protagonists of classical behaviourism agree that this school of psychology breaks down as a final philosophy because of its indefensible but necessary assumption that the objective facts of experience are unrelated to subjective experience. But in any event the whole question raised by Mr Lauwerys is completely irrelevant. Determinism, if need be, could flourish in the thickest undergrowths of a solipsist's mind

Mr Lauwerys states that it is the teleologist who insists that the future is immanent in the present In so far as the merits of a deterministic hypothesis are weighed by its value for purposes of prediction, this, by definition, is also part of the determinist's creed Mr. Lauwerys is simply making a false antithesis Merely agreeing that the prediction of the future is a worthy aim of science does not give to teleology any virtue that makes it necessary in scientific research

I am not prepared to say whether or not the category of final causation is a weapon of scientific analysis. If it is, Mr Lauwerys and those who agree with him have the task of showing that it can operate as such. At the moment, those who conduct their investigations according to everyday deterministic methods, without any appeals to teleology, are doing most, if not all, of the work of extending our reliable knowledge of phenomena

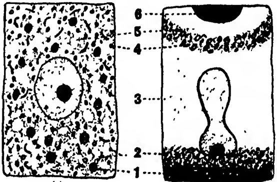
Effect of Ultra-Centrifuging on the Cells of the Root-Tip of the Bean

ROOT-TIPS of the bean were centrifuged in the Beams ultra-centrifuge at approximately 400,000 times gravity for twenty minutes. The effect is shown diagrammatically in Fig. 1. Fig. 1(*a*) is a control cell showing the normal distribution of the cytoplasmic components and inclusions. Fig. 1(*b*) represents an ultra-centrifuged cell showing the redistribution of the cytoplasmic components and inclusions into layers in the order of their relative and decreasing specific gravity, as follows: (1) a layer of starch grains and plastids (when present in the cell); (2) a layer of mitochondria (plastidome and pseudo-chondriome), (3) a layer of cytoplasm (which is often quite free of various cytoplasmic components); (4) a layer of osmiophilic platelets (Golgi bodies of Bowen), (5) a layer composed of, or formed by, the fusion of vacuoles and (6) a layer of lipoid material. Thus, it is evident from this study that the osmiophilic platelets are discrete



(*a*) (*b*)

Some Recent Atomic Weight Determinations

IN conjunction with Mr. H S Patterson, a number of new determinations of the limiting ratios of certain gases with oxygen have been carried out, using an improved microbalance apparatus in which errors due to adsorption have been eliminated. A more detailed account of the apparatus and results will be published elsewhere

The gases used were nitrous oxide, ethylene, carbon dioxide and carbon tetrafluoride. The measurements obtained from these gases lead to the following values of the atomic weights ·

$$N_{N_2O} = 14{\cdot}006(8). \quad C_{C_2H_4} = 12{\cdot}012(2)$$
$$C_{CO_2} = 12{\cdot}010(1). \quad F_{CF_4} = 18{\cdot}995.$$

The compressibilities at 21° C. of the gases can be calculated from the data and are appended below in comparison with the values obtained on an Andrew's compression apparatus[1].

Gas	$A_{21°C}$ microbalance	$A_{21°C}$ Andrew's apparatus
Nitrous oxide	0 00559	0 00567
Ethylene	0 00636	0·00612
Carbon dioxide	0 00522	0·00526
Carbon tetrafluoride	0·00418	0·00420

Whilst the values of nitrogen and fluorine are in close agreement with the accepted values, carbon

is distinctly higher than the accepted C = 12·00. Nevertheless, this high result, which indicates about one per cent of the 13 isotope, is in agreement with the spectroscopic work of Jenkins and Ornstein[5], and the value of C = 12·011 of Woodhead and Whytlaw-Gray[2]. Indeed, the agreement between our values from two entirely different gases and those of the other workers is so close that it seems very improbable that they are in error, and consequently that the true atomic weight of carbon is 12·01.

The value of F = 18·995 does not agree with the preliminary value of F = 19·01 which we published in these columns[4], using methyl fluoride. Consequently, these measurements have recently been repeated with the new apparatus. The new data lead to an atomic weight of F = 18·995 and a compressibility of $A_{21°C}$ = 0·0090. As would be expected, the adsorption error does not affect the compressibility to any marked extent. This last figure is in agreement with $A_{21°C}$ = 0·0088, measured on the Andrew's apparatus. It leads to $A_{0°C}$ = 0·0117, which does not confirm the value of Moles and Batuecas[5]. Consequently, our previous criticisms[6] still hold good.

Effect of Temperature on the Absorption of Crystals in the Infra-Red

IN a recent publication, Matossi and his collaborators[1] have investigated experimentally the influence of temperature on the absorption of crystals in the infra-red; this is to some degree an extension of the classical work of Rubens and Hertz[2].

A rather interesting point raised is that the fundamental feature of the earlier work—the distinction between regions sensitive and insensitive to temperature—may be spurious, and due to the shift with temperature of the band as a whole.

It is possible to say, however, that the distinction drawn by Rubens and Hertz does exist, though not in the form suggested by these investigators—that the 'inner' vibrations are the insensitive, and 'outer' vibrations the sensitive ones. The theory of the damping of the infra-red vibrations[3] shows that this is due to the coupling between the main vibrations and combinations of two other normal vibrations, and, further, that (*a*) the absorption on the short wave-length of the main vibration (λ_0) up to a point roughly $\lambda_0/\sqrt{2}$, is due to summation tones, and (*b*) the absorption on the long wave-length side is due to difference tones.

In the language of the quantum theory, the summation tones are produced by jumps from lower to higher quantum levels, whereas in a difference tone one of the jumps is from an excited to a lower level. It is obvious that, at very low temperatures, very few oscillators are in an excited state, hence the absorption due to difference tones must decrease to zero as the temperature decreases to zero.

It is also clear that absorption due to summation tones must be relatively insensitive to temperature, since at very low temperatures, where most oscillators are in the ground state, we can still have jumps from the ground state to excited states.

Hence the absorption on the short wave-length side of the main vibration should be relatively insensitive, that on the long wave-length side sensitive, to temperature. The distinction is obviously of the same kind as between the Stokes and anti-Stokes lines in the Raman effect[4].

There is unfortunately no experimental data in the region between λ_0 and $\lambda_0\sqrt{2}$, where one would expect the really interesting effects; it is to be hoped that experimenters will investigate this region as well as the other regions.

A more detailed treatment of the absorption in the infra-red will be given in a forthcoming paper.

Surface Tension of Urine during the Menstrual Cycle

WE have recently carried out in this laboratory surface tension measurements in connexion with the excretion of capillary-active substances in the urine of the normal human female. Over a period of twenty-eight days the surface tension of the first morning specimen each day was determined, and the centrifuged deposit examined microscopically for blood corpuscles, so that the onset of menstruation could be ascertained as early as possible. A typical curve of the variation is shown in Fig. 1, and from this the following interesting observations can be made.

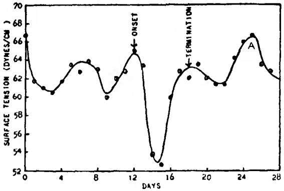

FIG. 1.

The curve consists of four phases corresponding in temporal relation to the four divisions into which—on physiological evidence—the human period can be divided, namely, resting, constructive, destructive and repair stages.

As regards the length and rhythm of cycle, it appears that the measurement of surface tension possibly provides a new means of estimating these hitherto inaccessible factors. For example, the curve shown is one of a cycle of length 25 days and of normal rhythm.

At the loop *A* on the diagram where one cycle ends

and the next commences, the surface tension attains a maximum value and capillary activity is at a minimum This corresponds in time to that period where, according to recent physiological investigations, ovulation probably occurs[1].

As regards the nature of the substances causing this variation of surface tension, we can at present say nothing definite It is known, however, that certain hormonic activities, such as excretion of prolan A near the midpoint of the cycle[2], are of a periodic nature, and it is, we think, legitimate to suggest that these causative substances are at least linked with the hormones responsible for the menstrual cycle

Further work is being carried out on these and kindred problems, a full account of which will be published shortly

Biological Formation of Ascorbic Acid

WE have already reported[1] that the spleen, kidney and liver tissues of the rat are able to form significant amounts of ascorbic acid, as determined titrimetrically, when incubated with mannose for three hours at pH 7·4 at 37° The brain, heart-muscle and leg muscle tissues of the rat have also been found to share this power, though to a less extent It has been possible, further, to extract the mannose dehydrogenase system from the spleen, kidney and liver tissues of the rat[2] A similar enzyme system has also been extracted from germinating *mung* (*Phaseolus mungo*), which can convert mannose into ascorbic acid at pH 5 8, but not at pH 7 4 This is perhaps related to the acidity of the germinating *mung*.

The ability with which the isolated tissues convert mannose into ascorbic acid *in vitro* differs considerably according to the species, as will be observed from the following table, which gives results obtained with liver tissue only

Species	Ascorbic Acid (mgm) formed per gm liver tissue after incubation with mannose for 3 hours at pH 7 4 at 37°
Rat	+0 300
Rabbit	+0 040
Pigeon	+0 053
Guinea pig (normal)	-0 030
Guinea pig (scorbutic)	-0 020
Monkey	-0 010

It will be noticed that the liver tissues of the rat, rabbit and pigeon—species known to be independent of an external source of vitamin C—are able to form ascorbic acid from mannose, whereas the liver tissues of the guinea pig, both normal and scorbutic, and monkey, which are dependent on an outside supply of vitamin C, are apparently unable to do so

It has generally been found that the other sugars studied, glucose, fructose, galactose, rhamnose, xylose and arabinose, are converted into ascorbic acid by the tissues of none of these animals under our conditions of experiment, with the exception that the liver tissue of the pigeon can convert glucose into ascorbic acid (0·033 mgm. ascorbic acid being formed per gm of the tissue). Preliminary experiments indicate the possibility that prolonged incubation of glucose with the liver tissue of the rat may also produce ascorbic acid

It is necessary to state that, in the absence of biological tests, which are presenting several technical difficulties, this work involves the assumption that the substance titrating with 2 6-dichlorophenol indophenol consists solely of vitamin C

Alleged Œstrogenic Activity of the Male Sex Hormone

CORRELATION of molecular structure of the sex hormones with that of the sterols and bile acids is now almost complete, and leads to the conclusion that the hormones are biological degradation products of cholesterol Adopting the working hypothesis that the male hormone (androsterone) is the immediate precursor of the female hormone (œstrone), a study of the action of various tissue extracts on androsterone has been commenced in the hope of converting this hormone into œstrone by biochemical means. The œstrus test gives a very sensitive method of detecting any such conversion.

The œstrogenic action of various testicular extracts[1] and male hormone extracts prepared from urine (for example, hombreol) has led to the suggestion that the male hormone has the same effect on the female genital tract as the female hormone[2]. If this were true, then of course the biological test would be valueless as a means of detecting dehydrogenation of the androsterone molecule. However, it is certain that the œstrogenic activity of male hormone preparations is due to the presence of substances other than this hormone, for no œstrogenic activity could be detected with pure crystalline androsterone prepared from cholesterol by the method of Ruzicka[3]

Four injections of 0·25 mgm. of androsterone, dissolved in sesame oil, were made into each of five ovariectomised mice at 12-hour intervals Vaginal smears were examined during 72 hours following the last injection, and showed no sign of œstrus These mice were afterwards given four injections of 0·25 γ of œstrone, and then showed a full œstrous response Two other castrated female mice received a total of 10 mgm each of androsterone with completely negative results Post mortem examination of these two animals showed no enlargement of the uterus or any other symptoms normally associated with the action of œstrogenic substances

The androsterone used in these experiments was generously presented by Ciba, Ltd , at the request of Prof Ruzicka

Mr. Mallock's Electrical Calculating Machine

READERS of NATURE may be interested in some details from my own experience of the electrical calculating machine invented by Mr. R. R. M. Mallock, constructed by the Cambridge Instrument Company, and mentioned in the issue of January 12, p. 63.

Through the kindness of Mr. Mallock and the hospitality of Mr. C. C. Mason, of Cambridge, I was privileged for a few days in October 1933 to see the machine at work. Being a little sceptical, I had provided myself beforehand with certain problems, for some of which I had solutions. I first proposed the solution of six simultaneous equations (coefficients all to 3 decimals), knowing the answers to be

0·866, − 0·415, 0·173, 0·337, − 0·126, 0·079

Under Mr. Mallock's direction I set up the coefficients on the switchboard while he connected the plugs. First approximations were quickly read off as 0·8711, − 0·4046, 0·1866, 0·3493, − 0·1246, 0·0659. Refinements gave in a few minutes the satisfactory results

0·8650, − 0·4149, 0·1722, 0·3370, − 0·1258, 0·0794.

Much of the time was taken up by questions and explanations, but I note from my records the total time as "11.48 a.m. to 12.26 p.m., 6/10/33". This very short time could have been greatly reduced.

On other occasions I observed the machine perform, to my proposals, the solution of algebraic equations, of characteristic equations of matrices (latent roots), the evaluation of determinants and of quadratic forms in several variables in specified regions, and cognate problems. It seems to me that in this realm, which is one of wide physical and statistical application, the machine has remarkable potentialities, and one hopes that its merits will gain it not merely the publicity, but also the opportunity for practical service which it awaits.

A. C. AITKEN

Points from Foregoing Letters

THE origin of the light of the aurora and of the night sky has been much debated. Prof. J. Kaplan states that he has succeeded in obtaining in the laboratory the green line λ5577, identical with that present both in the aurora and the light of the night sky. This he has done by means of a rapidly interrupted electrical discharge through nitrogen gas containing 1 per cent oxygen. The light emitted contained also other bands (Vegard-Kaplan system) which probably occur in the night sky.

Heavy and ordinary water differ in many of their chemical properties more than would be expected from the extra weight of the hydrogen atom present in the heavy variety. Mr. J. D. Bernal and Mr. G. Tamm ascribe these differences to the angular vibration (libration) of the molecules. Having calculated the energy associated with such libration, they find that it accounts for differences in the specific heat, and heats of evaporation and fusion of H_2O and D_2O, and also for the wave-length shift in the spectrum of light scattered by water.

By centrifuging the cells of the root tips of the bean, Dr. H. W. Beams and Mr. R. L. King note that various cell constituents arrange themselves in layers according to their specific gravity. They submit diagrams showing, among other things, that the Golgi bodies (platelets coloured black by osmium reagent) are in this way separated from the mitochondria (protoplasmic rods and granules), from which they cannot otherwise be readily distinguished.

From the density of several gaseous compounds of carbon (CO_2, C_2H_4, CF_4) compared with that of oxygen by means of a micro balance, Dr. W. Cawood concludes that 12·01 is a more exact value for the atomic weight of carbon, which would indicate the presence of about 1 per cent of the ^{13}C isotope. The compressibilities of those gases, based upon the newly calculated atomic weight, agree with those experimentally determined. For the atomic weights of nitrogen and fluorine, determined in the same way, the values 14·006 and 18·995 are given.

Dr. Blackman discusses in the light of the quantum theory whether, in the infra-red absorption spectrum of crystals, one should expect certain regions to be insensitive to temperature changes, as was experimentally stated to be the case by Rubens and Hertz. He concludes that the absorption on the short wave-length side of the main vibration should be less sensitive than that on the long wave-length side and appeals for further experimental work in this field.

Messrs. C. F. Selous and P. W. Perryman give a graph showing how the surface tension of urine varies during the menstrual cycle. It has a maximum value at the time when ovulation probably occurs and a minimum during menstruation, due possibly to the presence of hormones such as prolan A, the hormone stimulating the growth of the follicle containing the ova.

Dr. B. C. Guha and Mr. A. R. Ghosh report that not only the spleen, kidney and liver but also the brain and heart and leg muscle tissues of the rat have apparently the power of producing vitamin C (ascorbic acid) from the sugar-like substance mannose. They further find that the liver tissues of only those animals which are known to be independent of outside supplies of vitamin C can bring about the conversion of mannose into ascorbic acid. They have hitherto relied upon a chemical method of estimating the quantity of vitamin C produced.

Male hormone (androsterone) prepared from cholesterol (a common wax-like substance present in wool-fat, blood, etc.) has no effect upon the female genital tract according to Mr. F. L. Warren. This shows that the results obtained by previous investigators, who have reported that testicular extracts have the same effect on the female genital tract as the female hormone, must be due to some other substance present in those extracts. Mr. Warren suggests that the male hormone may be the immediate precursor of the female hormone and hopes to convert one into the other by biochemical means.

Research Items

Race and Constitutional Types. Studies of human morphological (constitutional) types have been made in accordance with a variety of methods, depending for the most part on inspection rather than measurement, with the object of determining the character and frequency of such types within a given population. It has been suggested, further, that the morphological type correlates with functional and psychic type to make a 'bio-type', and also with race. Thus in a study of the population of Germany, it has been found that, of Kretschmer's three types, the leptosome corresponds to the Nordic, the athletic to the Dinaric and the pycnic to the Mediterranean and the Alpine. An additional character would, therefore, appear to be afforded for racial classification. This method of analysis, however, hitherto has been applied only to Europeans. With the view of determining its value to the anthropologist, it has now been applied to natives of Indo China and Madagascar by Dr. G. Machado da Sousa (*L'Anthropologie*, **44**, No. 5–6). It would appear that the classification based upon European material does not hold good when applied to other races, the combination of characters of which the types are composed being different, while of the methods employed two only, those of Viola and of Manouvrier, were found suitable. It appears, however, that among the natives of Indo China there is no correspondence in the types obtained by the two methods. As regards characters, among the Indo-Chinese, cranial form and morphological type do not correspond; but, on the other hand, there is a certain relation between the type and the form of the face. Generally, there would appear to be no correlation between racial type and constitutional type, though it is possible in the two races under consideration to recognise two extreme types of individual morphology.

Problem of Immunity in Cancer. Dr. M. J. A. des Ligneris has recently described researches carried out to investigate whether the serum of animals treated by injections of cancerous tissues acquire specific antibodies to malignant cells (*Pub. South African Inst. Med. Res.*, No. 34. "Studies on Cell Growth (2) The Growth *in vitro* of Normal Mouse Cells and of Mouse Cancer Cells (Carcinoma, Sarcoma) in Neutral and Immune Media (Serum plasma)"). Dr. des Ligneris inoculated two sheep eight times each, at intervals of 8–10 days, with crushed mouse carcinoma (63 of the Imperial Cancer Research Fund), and two similar sheep at the same times with crushed normal organs of healthy mice. Fragments of normal mouse organs (spleen, lungs, liver and kidney), of mouse carcinoma 63, and of mouse sarcoma 37 were grown in tissue cultures, employing sera and plasma obtained from normal rats, fowls, rabbits and sheep. Upon these cultures was tested the action of sera and plasma from the inoculated sheep. Of the results of these experiments Dr. des Ligneris says that they "clearly show that, in the serum of sheep treated with repeated injections of mouse carcinoma tissue, the developing antibodies have, for all practical purposes, none other than anti-species characters; it was not possible to detect in these sheep sera any kind of antibody capable of showing any specifically 'anti-malignant' characteristics".

Early Development of the Ferret. W. J. Hamilton describes (*Trans. Roy. Soc. Edin.*, **58**, 251–278; 1934) the early development of the ferret, based on the examination of living and of fixed material. The egg is richly supplied with fat in the form of globules. At one pole of the egg is a cytoplasmic crescent, covering about one half of the egg, and here the fat globules are less densely present. In life, the zona pellucida appears as a homogeneous membrane, surrounding the perivitelline space in which the egg can rotate. The first cleavage produces two cells similar in appearance but not equal in size, and their next division is not synchronous, hence a three-cell stage is produced. In the four cell stage the cells are usually arranged in the form of a cross, and one of the cells was found to be smaller than the other three. At the sixteen cell stage one cell is centrally placed; it has the same morphological characters as the other cells and the fat is equally distributed among the cells. A little later a cavity—the blastocoel—arises as an intercellular space or by the fusion of intercellular spaces. The blastocyst increases very rapidly in size, the trophoblast becomes attenuated and the inner cell mass (produced by the division of the central cell of the sixteen-cell stage) becomes lenticular and later forms the embryonic disc. The central cell mass is attached at one point to the trophoblast and the disappearance of the covering trophoblast takes place relatively early in the ferret. Endoderm cells arise from the convex surface of the disc as a continuous layer; they are at first flattened but later, under the anterior part of the embryonic disc, they become columnar, forming the prochordal plate. Fat is found in the embryonic ectoderm and in the trophoblast, but not in the endoderm cells. The paper is illustrated by eighty photomicrographs.

Insects and Spiders from East Greenland. In the *Annals and Magazine of Natural History* of December, Mr. David Lack contributes a short account of some insects obtained by the Cambridge expedition to Scoresby Sound in lat. 70° N. Most of the collection was made around Hurry Inlet, a subsidiary fjord running north from Scoresby Sound, on August 1–15. The list given by Mr. Lack includes all the orders of insects collected, excepting the Diptera which are not yet identified, and various specialists are responsible for the names given. Of the eight species of Collembola recorded, four are new to Greenland; one species of Lepidoptera is new to science and one other species, together with a single species of Aphididæ, have not been previously recorded from Greenland. Two other species of Lepidoptera, it may be added, are new to east Greenland, but were previously known from west Greenland. All the other species listed were already known from east Greenland. The present collection emphasises the poorness of the insect fauna of east as compared with west Greenland. The Ichneumonids collected by the expedition form the subject of a separate paper by Mr. M. A. Roman, of Stockholm, in the same issue of the journal. They are represented by eleven species, of which one, and the female of another species, are new to science. A third paper by Mr. A. Randell Jackson deals with the spiders, of which there are thirteen species. Among these latter, five appear to have been previously unrecorded from

Greenland, including one new species. The general conclusion is that, so far as is at present known, the spider fauna of Greenland is mainly American, which may be contrasted with that of Iceland, which is mainly European.

Fossil Starfishes. The *Proceedings of the Royal Society of Victoria*, 46 (New Series), Part 2, May 1934, contains two interesting papers on fossil star fishes "A Lower Cretaceous Brittle-star from Queensland" by Frederick Chapman, and "The Palæozoic Starfish of Victoria" by Robert B Withers and R A Keble The brittle-star is a new species of *Ophiacantha, O (Ophioglyphoida) fosteri*, found on the fractured faces of a bore-core obtained at Cleeve, near Longreach, Queensland The Asteroidea are dealt with in the second paper There are now fifteen recognisable species known from Victoria, of which ten are new They are all from the Silurian, and are distributed over eight genera ; *Hudsonaster, Caractacaster, Promopalæaster* and *Petraster* are restricted to the Ordovician in England and America , *Urasterella, Salteraster* and *Schuchertia* begin in the Ordovician, but range into the Silurian *Palasterina* alone of the eight genera does not occur elsewhere lower than the Silurian As the authors state, "this would seem to indicate that asterid distribution started from a point in the Northern Hemisphere"

Cytological Studies in Pears. In a recent paper (*J Pomol and Hort Sci*, 12, No 4, pp 321–326, December, 1934), Mr A A Moffett, of the John Innes Horticultural Institution, reports an interesting study of the cytology of thirty four varieties of pear Chromosome numbers of these varieties have been determined Twenty-seven diploids, each with 34 chromosomes, and seven triploids, with 51 chromosomes, have been found The triploids are relatively infertile, and, apart from the variety Pitmaston Duchess, are not cultivated extensively This is partly due to the unequal reduction of the triploid at the formation of gametes , but the paper under review shows that there is a marked difference in the vigour of the pollen Pollen from a diploid plant usually germinates readily, the greater number of varieties having a pollen germination of more than 50 per cent, while pollen from a triploid rarely attains more than 25 per cent germination

Temperature and Humidity near the Ground in India In a paper on micro-climatology by L A Ramdas, which appeared in *Current Science* of May 1934, reference is made to some interesting facts concerning the diurnal variation of the air temperature and the pressure of aqueous vapour in the first few feet above the ground In temperate latitudes, as is well known, the surface turbulence set up by solar radiation during the day tends to die out completely on clear windless nights, when the air becomes stratified and the lowest temperature is to be found on the ground itself Judging from the results obtained at Poona, this is not generally the case within the tropics, even in winter, for the accumulated solar heat there is great enough to maintain a layer of turbulence all through the night, although a very shallow one compared with the layer at its maximum development in the afternoon. An unexpected result was also obtained in connexion with the pressure of aqueous vapour, which showed a minimum close to the ground at night in the autumn, although in sunny weather evaporation from the ground tended to give a maximum near the ground, as was to be expected The explanation was apparent when measurements were made of the water content of samples of surface soil exposed under natural conditions , it appears that the surface soil became sufficiently desiccated by evening in the autumn to become an absorber of water vapour at night, and that this was the cause of the night minimum close to the ground The two phenomena together resulted in the layer of deposition of dew beginning at some height between six and twelve inches, and in an increase of the amount with height above the ground

Isotopic Ratio of Oxygen and the Atomic Weight of Hydrogen. It has been pointed out that in the paragraph appearing under the above heading in NATURE of December 22, p 977, the term "atomic weight of hydrogen" was used throughout instead of "the mass of the hydrogen isotope, H^1" It may be mentioned that the research was undertaken to discover where the discrepancy between the chemical atomic weight of hydrogen (1 00777) and the mass of the hydrogen isotope, H^1 (1 00756, on the scale O = 16), lay The hydrogen used for the best atomic weight determinations has been obtained electrolytically, and contains a very small proportion of the heavy isotope, H^2 (H^1 : H^2 = 30,000 : 1) Its atomic weight should therefore approximate closely to the mass of the hydrogen isotope, H^1 The re-determination of the isotopic ratio of oxygen gives the value 1 00763 for the mass of the isotope, H^1, which is nearer the chemical value

Experiments with Positrons. In a paper contributed to the German Physical and Mathematical Conference at Pyrmont in September 1934 (*Phys Z*, 35, 999, 1934), E Rupp describes a number of fundamental experiments with positrons An apparatus for the artificial production of positrons is described Accelerated protons impinge on a layer of lithium within a hemispherical cup of aluminium foil. α-Rays emitted from the lithium strike the aluminium, and give rise to positrons The positrons obtained had velocities varying from 800 to 1,000 kilovolts. The value of the ratio of the charge to the mass was determined by applying a magnetic and an electric field in the usual way, and was found to be identical, within the limits of experimental error, with that for electrons An attempt was made to determine the mass of the positron by studying the diffraction of positrons at aluminium and gold foils. Assuming that the positron, like the electron, is associated with a wave-motion, it would be expected that the relationship $\lambda = h/mv$ would hold, λ being the wave length, m the mass, and v the velocity of the positron, and h Planck's constant It was found, however, that no definite diffraction occurred, but there was a continuous scattering The absorption of positrons by aluminium, copper and gold foils was also investigated To a first approximation, the absorption is proportional to the atomic weight of the absorbent. The production of X-rays by bombardment of anticathodes by positrons was studied The X rays obtained from all the substances investigated (gold, copper, silver, graphite, rock-salt and galena) were monochromatic, the wave-length being independent of the velocity of the positrons The X-rays from all the substances examined had the same absorption coefficient, which is thus a characteristic of positrons, and not of the substance used as the anticathode

Pittsburgh Meeting of the American Association

THE ninety-fifth meeting of the American Association for the Advancement of Science was held at Pittsburgh on December 27–January 2, and during the week members of this and associated organisations numbering nearly four thousand participated there in a most successful series of meetings Joined with the city as hosts were the Carnegie Institute of Technology, the University of Pittsburgh, the Pennsylvania College for Women, Duquesne University and the Mellon Institute Dr Thomas S Baker, president of the Carnegie Institute of Technology, was chairman of the local committee and Dr Davenport Hooker, of the University of Pittsburgh, vice-chairman Arrangements for sessions were admirably provided in the group of academic and public buildings in the Schenley Park centre

Two previous meetings have been held in Pittsburgh, both of them marked by events of especial significance in the history of the Association The first in June 1902 was the last of the fifty one summer meetings, at it was adopted a new plan for mid-winter Convocation Week meetings, bringing together a large group of scientific organisations, the first of which was held in Washington in the following December This plan, which has been followed ever since, has served well to develop scientific work and influence in the country The second Pittsburgh meeting was held in December 1917 with a programme devoted to national preparedness and effective participation in the War. It exercised an important influence on the country at this crucial period

Pittsburgh played a prominent part in early colonial history. Its strategic location and the immense value of the natural resources of the region gave support to the later initial enterprises in manufacturing lines, and led to the development of mining and other industrial activities on the immense scale that characterises this region to-day The secret of its success has been the application of science to the utilisation of natural resources. In consequence, it offers attractions to scientific organisations which were well utilised in planning and carrying out the programme of the meeting

In all, forty-two affiliated societies met in conjunction with the fifteen sections of the Association. The programmes were replete with papers of striking value, and attendance was larger than for several years past. A few of the outstanding features may be mentioned briefly

The evening general sessions were held in the Carnegie Music Hall On December 27, President Thorndike presided and responded to the addresses of welcome from the city and the universities The address was given by Dr. William A White of the U.S Public Health Service on "Man, the Great Integrator", it was illustrated by examples from the field of psychiatry showing the reciprocal relation of the world within and the world without, it demonstrated how psychiatry, like general science, has discarded many of the older traditional ways of thinking and as a result has discovered a new world of thought and knowledge of great significance to the understanding of man and to culture in general.

On December 28, Prof. E A. Hooton of Harvard delivered the Sigma Xi address on "*Homo sapiens*, Whence and Whither" On December 29, Dr. Charles F Kettering, director of General Motors Research, spoke on "Some Future Problems of Science and Engineering" On December 31 came the address of the retiring president of the Association, Dr. Henry Norris Russell of Princeton, on "The Atmospheres of the Planets" [see p. 219] The Josiah Willard Gibbs lecture was given by Prof. Albert Einstein [see NATURE, Jan. 19, p. 111]

Among special afternoon lectures was one to mark the quarter centennial of the discovery of the north pole It was given on December 27 by Prof Wm H. Hobbs of Michigan on "The Career of Admiral Peary, the Discoverer of the North Pole" Prof. H H Newman of Chicago delivered an illustrated address on December 28 on "Twins Reared Apart and the Nature Nurture Problem" On December 28 also, W R Chapline of the U S Forest Service lectured on "Forestry fosters New Approaches to Watershed Conservation", describing with sound films researches of the U S Forest Service dealing with stream-flow and erosion problems on forest and range lands On December 29, Prof M H Liddell of Purdue spoke on "The Acoustics of the Auditory Spectrum", and was assisted by Prof C T Knipp of Illinois, who demonstrated the Knipp singing tubes. On December 30, Dr Phillips Thomas of the Research Department of Westinghouse, under the title "Ramblings in Research", gave a remarkable demonstration of recent discoveries not previously presented publicly.

The American Society of Naturalists in its annual symposium dealt with "Cytogenetic Evolutionary Processes and Their Bearing on Evolution Theory". Prof A F Shull of Michigan took as the subject of the presidential address "Weismann and Haeckel: One Hundred Years".

The Committee on the Place of Science in Education presented programmes of invited papers at two sessions, and had a largely attended luncheon, after which Dr E L Thorndike, president of the Association, spoke on "Psychology of Attitudes"

Many symposia and joint sessions were arranged by various sections and affiliated societies In one, the Ecological Society of America with the Society of American Foresters included an invitation paper by Dr R. Maclagan Gorrie on "The Work of the Forest Research Institute, Dehra Dun, India", illustrated by fine moving pictures. A symposium on science and the Press was largely attended [see p. 239]

The production of active immunity against poliomyelitis was reported in papers by Dr. Maurice Brodie of New York City and by John A Kolmer of Temple University, and a series of invited papers on sulphur-containing compounds in their relation to cancer, arthritis, muscular dystrophy and cystinuria were presented in two especially important symposia in the Section of Medical Sciences.

The twelfth annual American Association prize of one thousand dollars was unanimously awarded by the committee to Dr. Vern O. Knudson of the University of California at Los Angeles, for his paper entitled "The Absorption of Sound in Gases". Dr. Knudson has cleverly adapted methods employed in acoustics to the important domain of molecular interactions Above a frequency of 4,000 cycles per

second the attenuation due to the absorption of sound in oxygen is so rapid that it decreases to a millionth of its initial intensity in travelling a distance of 60 m In an atmosphere of oxygen the consonants of high frequency in speech sounds could scarcely be heard across an ordinary street The absorption of sound in a room at high frequencies is more influenced by the humidity and temperature of the air than by the absorbing boundaries of the room or the audience The 'acoustic transparency' of the air at any temperature and humidity can be calculated A new technique is furnished for investigating not only the nature of molecular collisions but also the nature of the molecular forces involved

The only foreign delegates present at the meeting were the representatives of the South African Association for the Advancement of Science and the Royal Society of South Africa; they were Prof H B Fantham and Mrs Fantham (Dr. Annie Porter), of McGill University, Montreal

The new Committee on Organisation recommended that the Council promote the establishment of local branches, as long since provided for in the constitution It was voted to encourage the formation of such branches under the direction of the general secretary On application of a group of seventy-five persons such a branch was established at Lancaster, Pa, and steps taken to assist in the organisation of other places.

By the courtesy of the Mellon Institute, the annual science exhibition occupied an entire floor of the splendid new building of the Institute The exhibits of the National Bureau of Standards on deuterium and its compounds from twenty-five co-operating laboratories, the Bartol Research Foundation exhibit of cosmic ray apparatus, and the Columbia University demonstration of the production of artificial radioactive substances stood out among a long series of unusual research exhibits for their truly remarkable character

The addresses of the retiring vice presidents, given at various times, included the following. *Mathematics*, Prof Charles N Moore of the University of Cincinnati, on "Mathematics and Science"; *Physics*, Dr. Clinton J Davisson of the Bell Telephone Laboratories, New York City, on "Electron Optics"; *Chemistry*, Prof. Arthur B Lamb of Harvard University, on "Crystallogenetic Adsorbents"; *Astronomy*, Dr Vesto M Slipher of Lowell Observatory, Flagstaff, Ariz, on "The Atmosphere of the Planets as Inferred from Their Spectra"; *Geology and Geography*, Dr. Rollin T. Chamberlin of the University of Chicago, on "Certain Aspects of Geologic Classifications and Correlations", *Zoology*, Dr. George L. Streeter of the Carnegie Institution, Baltimore, Md, on "The Education of an Anatomist"; *Botany*, Dr Karl M Wiegand of Cornell University, on "A Taxonomist's Experience with Hybrids in the Wild", *Anthropology*, Dr. T. Wingate Todd of Western Reserve University, on "Anthropology and Growth", *Psychology*, Dr Walter R Miles of Yale University, on "Training, Practice and Mental Longevity", *Education*, Prof Walter F Dearborn of Harvard University, on "The Mental and Physical Growth of Public School Children", *Social and Economic Sciences*, Prof Wesley C. Mitchell of Columbia University, on "The Social Sciences and National Planning", *Engineering*, Dr Charles F Kettering of the General Motors Corporation, Detroit, Mich., on "Some Future Problems of Science and Engineering", *Medical Sciences*, Dr Cyrus C Sturgis of the University of Michigan, on "Review of Some of the More Recent Advances in the Study of Blood Diseases", *Agriculture*, Dr Albert R Mann of Cornell University, on "The Agricultural Significance of State and National Planning"

The following officers were among those elected for the year 1935 *President*, Prof Karl T Compton of Massachusetts Institute of Technology, *General Secretary*, Prof Otis W Caldwell of Teachers College, Columbia University, *Vice Presidents of the Sections* Prof T H Hildebrandt of the University of Michigan (Mathematics), Dr John T Tate of the University of Minnesota (Physics), Prof Moses Gomberg of the University of Michigan (Chemistry), Dr H. R. Morgan of the U S Naval Observatory (Astronomy); Prof Walter E McCourt of Washington University (Geology and Geography), Dr Oscar Riddle of the Station for Experimental Evolution, Cold Spring Harbor, N.Y. (Zoological Sciences), Prof E. W. Sinnott of Columbia University (Botanical Sciences), N C Nelson of the American Museum of Natural History, New York City (Anthropology), Joseph Peterson of George Peabody College for Teachers, Nashville (Psychology), Shelby Harrison of Russell Sage Foundation, New York City (Social and Economic Sciences), Dr George Sarton of Harvard University Library (Historical and Philological Sciences); H N Davis of Stevens Institute of Technology, Hoboken, N J (Engineering), Stanhope Bayne-Jones of Yale University Medical School (Medical Sciences), H K Hayes of the University of Minnesota (Agriculture); Prof F. B Knight of the University of Iowa (Education)

HENRY B. WARD

Science and the Newspaper Press in the United States

ONE of the leading features of the recent meeting of the American Association for the Advancement of Science held at Pittsburgh, Pennsylvania, was a symposium on the relation between science and the Press. Although within the past decade Press reports of scientific work have become far more satisfactory than formerly, and distrustfulness of the Press on the part of scientific men has been greatly reduced, certain difficulties still exist The object of the symposium was to bring these difficulties frankly into the open, in the hope that recognition and subsequent discussion might lead to their eventual removal.

The speakers at this symposium were Dr Karl T. Compton, president of the Massachusetts Institute of Technology, who is president elect of the American Association; Mr David Dietz, science editor of the Scripps-Howard Newspapers, and president of the National Association of Science Writers, Cleveland, Ohio; Mr. Robert D Potter, Science Service, Washington, District of Columbia, speaking for the director, Mr. Watson Davis; Dr. Edward R. Weidlein, director of the Mellon Institute for Industrial Research, Pittsburgh, Pennsylvania; Mr. William L. Laurence, science news editor, the *New York Times*, New York; Dr. Benjamin C. Gruenberg,

American Association for Adult Education, New York; Mr Gobind Behari Lal, science editor, Hearst Newspapers, New York, Mr Thomas R. Henry, staff correspondent, the *Washington Star*, Washington, and Mr Howard W Blakeslee, science editor, the Associated Press, New York It is expected that the contributions of these writers and others will be published in a forthcoming number of *Science*

It was gratifying to note the interest taken in this symposium by the members of the Association, and to observe the co-operative spirit—indeed, the cordial relationship—that now exists between the scientific men and the representatives of the Press For it is only within the past few years that science and the Press have come really to understand and to appreciate each other

The present system of reporting science in the Press of the United States may be said to have had its inception in 1921 In that year, the late Mr Edward Willis Scripps established the organisation known as 'Science Service', which had as its object making "the greatest use of the press in the way of disseminating the knowledge which is the result of painstaking research carried on by a few hundred, or at least a few thousand, well trained men with great mental capacity" In the same year the Scripps-Howard newspapers appointed Mr David Dietz as science editor, and Mr Alva Johnston was selected to write the articles on science for the *New York Times*

The Boston meeting of the Association in 1922 was reported to the Press by Science Service, Mr Dietz and Mr Johnston For his work in reporting this meeting Mr Johnston was awarded the Pulitzer prize of one thousand dollars for "the best job of reporting done during the year" The award naturally attracted attention to science writing, and within the next few years several other newspapers, among them the *Washington Star*, the *New York Herald-Tribune* and the *Detroit News*, designated young men of outstanding ability as scientific writers for them

In 1927 the Associated Press, a co-operative Press association furnishing news to about 1,300 newspapers, appointed two of its ablest young men as science editors, whose duty it was to write science exclusively for the member newspapers In selecting the men for these positions, Mr Kent Cooper, the general manager, adopted the principle that the best results in writing science for the Press are to be obtained by men who are, primarily, trained journalists of exceptional ability This principle has proved to be sound, and has been generally followed by the Press in the United States

In April 1934 there was organised the National Association of Science Writers, with the membership limited to staff members of newspapers and press associations who devote their major efforts to science The purpose of this Association is "to foster the dissemination of accurate scientific knowledge by the press of the Nation, in cooperation with scientific organisations and individual scientists" The charter members were twelve in number, representing the Associated Press (2), Science Service (2), the Scripps-Howard Newspapers, the *Philadelphia Inquirer*, the *Washington Star*, the *New York Times* (2), the Hearst Newspapers, the *New York Herald-Tribune* and the *Detroit News*. One honorary member was elected. Mr David Dietz, science editor of the Scripps-Howard Newspapers, who is a fellow of the Royal Astronomical Society and has attended and reported meetings of the British Association, was elected president.

The growth of interest in science on the part of the Press of the United States is well shown by the fact that at the recent Pittsburgh meeting of the Association there were sixteen science writers from other cities, ten of them members of the National Association of Science Writers At the meeting in Boston in the preceding year there were ten from other cities At the Boston meeting in 1922 there had been only four

Appreciation of the excellent work the science writers connected with the daily Press are doing is being shown in many different ways As examples it may be mentioned that during the past year the commencement oration at the Massachusetts Institute of Technology, at Cambridge, Massachusetts, was delivered by Mr Howard W. Blakeslee, science editor of the Associated Press, and the commencement oration at the Carnegie Institute of Technology, at Pittsburgh, Pennsylvania, was given by Mr Waldemar Kaempffert, science editor of the *New York Times* Also, Mr. Thomas R Henry, science writer for the *Washington Star*, was elected a member of the Washington Academy of Sciences as an appreciation of his work, and shortly thereafter addressed the Academy on the relation between science and the newspapers

In the United States, the newspapers have now become an important element in the scientific complex of the country They are by far the most important intermediary between those who are engaged in scientific work and the public at large. As such, they are the most important factor, so far as science is concerned, in what is commonly called adult education It is a pleasure to be able to state that they appreciate their responsibilities and are doing everything in their power, at no small expense to themselves, for the common good

University and Educational Intelligence

BIRMINGHAM—The Huxley Lecture is to be delivered on March 14 at 5 30 p m in the medical theatre by Sir Thomas Lewis, who has chosen for his subject "Clinical Science within the University".

CAMBRIDGE—Prof Othenio Abel, recently appointed professor of geology and palæontology in the University of Göttingen, will give three lectures on palæobiology and evolution in the Department of Zoology at 5 p m on February 11, 13 and 15.

The Faculty Board of Archæology and Anthropology has appointed T T Paterson, of Trinity College, and J R B Stewart, of Trinity Hall, to Anthony Wilkin studentships.

LONDON—The County Borough Council of Croydon is making a grant of £10,000, payable over ten years, towards the erection of new buildings in Bloomsbury, and the Westminster Bank has granted £500 for the same purpose

OXFORD.—The scientific work of early members of Oriel College was the subject of a public lecture by Dr. Gunther on February 2. The benefactions to the library and list of graduates show that medical studies flourished there at the end of the sixteenth

century, when Thomas Coghan wrote his "Haven of Health", for the welfare of students living in Oxford. Special mention was made of the work of Hariot the mathematician, of Merrett and Dyer among botanists, and finally of Gilbert White and of those Tractarians who attended scientific lectures

At a meeting of Congregation to be held on February 12, details of the establishment of a museum of the history of science will be presented It is suggested that the museum shall consist of the collection of scientific instruments and books presented to the University by the late Mr Lewis Evans in 1924, any additions made to the collection since 1924, and any further additions of objects and books illustrating the history of science, with special reference to scientific work in Oxford, as may be accepted or acquired by the University after the passing of the statute A committee, consisting of the Vice-Chancellor, the proctors, and six others, would be appointed The duties of the committee would be to appoint a curator of the museum, to accept or otherwise acquire, outright or on loan, objects and books illustrating the history of science, and to formulate rules for the governing of the museum.

Science News a Century Ago

The Royal Geographical Society

At a meeting of the Royal Geographical Society held on February 9, 1835, an extract was read from the private journal kept by Mr. Oldfield, late surgeon with Mr. Lander, detailing the circumstances which attended the attempt made by the expedition to ascend the Tshadda (Benue), the great eastern confluent of the Quorra (Niger). From these it appeared that the chief difficulty arose from the alarm, and consequent hostility, of the natives, which made it impossible to obtain supplies of provisions. Otherwise the stream, though rapid, running at the rate of 2½ knots, was easily ascended by the steamer, and though navigation of the river was uncertain, the bed of the river being thickly set with small islands and shoals, it was not difficult, and appeared even clearer where the expedition stopped than lower down The utmost extent reached was 110 miles

Chesney's Expedition to the Euphrates

A century ago both the British and Indian Governments were taking steps to further the project of shortening the passage to India by means of steam navigation. In connexion with this, Col. Francis Rawdon Chesney (1789–1872) was entrusted with the task of exploring the route via the Euphrates. For this expedition, Laird's of Birkenhead constructed two small iron steamers, the *Euphrates*, 105 ft. long, 50 h.p., and the *Tigris*, 86 ft. long, 20 h.p., which were to be conveyed to Syria and transported in sections across the desert to the banks of the Euphrates. When ready, the steamers were stowed aboard the sailing vessel *George Canning*, which left Liverpool on February 11, 1835, with some of the members of the expedition Writing of this event, the *Athenaeum* said that it was intended that the *George Canning* should call at Cork, from which place she was to be escorted to the River Orontes by H.M. Steam Vessel *Alban*. Some workmen from Laird's accompanied the expedition, which included also some artillerymen who had been instructed in iron working

While the main object of the expedition was to survey the Euphrates as far as the Persian Gulf, attention was not to be entirely confined to steam communication, for it would provide opportunity, said the *Athenaeum*, "to make the necessary examinations of that celebrated part of the world, where the first human formations may be looked for with confidence" The expedition met with many difficulties and it was not until March 16, 1836, that the steamers began the descent of the river On the passage down, the *Tigris*, with all her journals and surveys, was lost, and Chesney was nearly drowned He, however, continued the voyage in the *Euphrates* and on June 19, 1836, reached the Indian Ocean His account of the expedition was published in 1850

Matthias Baldwin's Locomotives

No one in America contributed more to the improvement of the locomotive than Matthias Baldwin (1795–1866), who in 1835 transferred his works from Minor Street, Philadelphia, to Broad Street The Franklin Institute was much interested in his work and on February 12, 1835, the committee on science and the arts of the Institute submitted a report on the locomotives he was then building, in which it found "numerous improvements affecting nearly every part of the machine". The report made special mention of his improvements in the valves, the feed pumps, the reversing gear and the axles and wheels Mr. Baldwin, it was stated, "has completed several engines, one of them may be seen in operation on the Philadelphia and Trenton Rail-road, and four on the state road to Columbia; all of which, as well as one in use at Charleston, South Carolina, have given entire satisfaction by their performance

The Committee are informed that some of these improvements have been secured to their inventor by patents, and that he richly deserves to reap the benefit of them, will be admitted by any one who is aware of the extensive use and increasing demand for these costly structures "

Lyell and the Geological Society

At the anniversary meeting of the Geological Society held early in February 1835, the Wollaston Medal was awarded to Gideon Mantell (1790–1852), the Lewes surgeon who had made a close study of the chalk formations in Sussex. The meeting was followed by a dinner, of which Lyell, the president of the Society, wrote to Mantell: "The dinner went off famously, more than a hundred present. After the toasts had been given of the King, Royal Family, Geological Society, late president and president, I gave you I send you a copy of my speech almost word for word as delivered. . . I assure you I had the feeling of the meeting with me, and in some respects it produced a better effect than if you had been there It was by far the longest toast given, but I am sure they were not tired. Lord Lansdowne, who was on my left hand, asked all about you. I got him to give Oxford and Buckland. Fitton gave Cambridge, followed by Sedgwick; Sedgwick the Royal Society, answered by Lubbock, Buckland the Linnean; I the Astronomical, answered by Baily; Greenough the Geographical, answered by Murchison. We then drank Burnes who made a good speech "

Societies and Academies

London

Royal Society, January 31. R. T. Hill and A. S. Parkes: Hypophysectomy of birds. (6) Plumage changes in hypophysectomised fowls. Hypophysectomy of the Brown Leghorn cock results in the loss of most or all of the black pigment from the feathers of the under-neck, breast and legs. The later growing feathers, particularly, are usually devoid of black and may be extensively fringed. The new plumage over the rest of the body is characterised by loss of black pigment and increase of fringing due to lack of barbules. These changes are so similar to those which follow thyroidectomy that they may reasonably be supposed to be due to thyroid deficiency, which is well known to follow hypophysectomy in mammals. (5) Effect of replacement therapy on the gonads, accessory organs and secondary sexual characters of hypophysectomised fowls. Fowls injected with ox anterior lobe extract for 4–6 days after hypophysectomy all showed a temporary increase in the size of the comb and, in the male, the atrophy of the testes was slightly retarded. Prolonged injection after operation, however, failed to avert (a) the comb shrinkage, (b) the testes atrophy, or (c) the plumage changes, which follow hypophysectomy. Attempts to restore the atrophied gonads and combs of hypophysectomised birds by injections of anterior lobe and urine of pregnancy extracts were comparatively unsuccessful. H. Muir Evans: The brain of *Gadus* with special reference to the medulla oblongata and its variations according to the feeding habits of different Gadidæ (1 and 2). The divergence of opinion of the significance of the various lobes in *Gadus* has necessitated a detailed microscopic examination of serial sections of the medulla of the whiting, the result of which is to confirm the views of Goronowitsch and others, and to dispute the conclusions of C. J. Herrick. The facial lobes described by the former writers are held to be true facial lobes, comparable to the single facial lobe of the roach, as a type of cyprinoid brain, which is the result of the fusion of two facial elements. Different species of gadoids can be classified according to their diet, and both diet and dentition are reflected in the pattern of the medulla oblongata. At one extreme is the haddock, feeding on crustacea and mollusca, with a large facial lobe and a small somatic sensory lobe, and at the other end species like the ling and the pollack, feeding almost entirely on fish, with a small facial lobe and a very large somatic sensory lobe. In between there is a gradual transition both in types of medulla and in feeding habits, as we pass from the haddock to the cod, whiting, ling, pollack and hake. H. W. Florey and H. E. Harding: A humoral control of the secretion of Brunner's glands. The secretion of Brunner's glands of the cat occurs independently of extrinsic innervation. The glands are activated after the taking of food by a blood-borne stimulus—a hormone or secretagogue.

Paris

Academy of Sciences, December 26 (*C.R.*, 199, 1537–1694)*. Louis Médard: The Raman effect of binary mixtures of sulphuric and nitric acids. A line with frequency about 1,400 cm.$^{-1}$, very intense even with very low concentrations of sulphuric acid (0·005 per cent), is described. This is called the sulphonitric line. Letort: The kinetics and energy of activation of the thermal decomposition of the vapour of acetaldehyde. Raymond Charonnat: Researches on the reaction of J. H. de Boer. Study of the alizarin-zirconyl complex and its reaction with fluorides in acid solutions. Georges Denigès: The micro-estimation of caffeine by colorimetry. A modification of Weidel's reaction giving quantitative results. M. Tiffeneau and Mlle. B. Tchoubar: The vinylic and hydrobenzoinic dehydration of the α-cyclane-glycols. The extension of the hydrobenzoinic transposition to the cyclane series. Mlle. S. Caillère: Study of the dehydration of the fibrous parasepiolite of Madagascar. Scientific Adventure and Social Progress

THE national lecture by Dr T R Glover on the challenge of the Greek, broadcast on December 19, vividly recalls in its plea for the classical discipline one of the most suggestive passages in Prof A N Whitehead's "Adventures of Ideas" In brief compass, Dr Glover set forth the antithesis which Greek customs, ways of living and outlook on life present to those characteristic of this age, and suggested certain aspects of Greek life which are worthy of our consideration

The five aspects discussed by Dr Glover are so interrelated that an attempt to differentiate between them in order of importance is largely beside the mark Few to-day, for example, whether interested principally in science, in art, in industry, in politics, or in society as a whole, would deny the fundamental importance of creative thought as the mainspring of constructive action, or that such thought is one of our most urgent needs This pre-eminent characteristic of the Greeks cannot, however, be dissociated from their capacity to interpret life, to see life steadily and to see it whole, from their essential young-mindedness and adventurousness, their individuality and passion for self-expression, their freedom of enterprise

The tragedy of the present day lies largely in the senility of mind with which, over whole ranges of industrial, social and political problems, we are confronting opportunities which are stupendous compared with those possessed by the Greeks There is scarcely a field of human enterprise and thought, from the unemployment situation, disarmament and tariffs to transport or county planning, in which the powers and opportunities given into our hands by science are not being misused, abused or lost through lack of courage and magnanimity Truly did the prophet exclaim "where there is no vision the people perish"

This inelasticity of mind has two consequences It limits or even excludes the experiments which younger and more adventurous minds would make, and it severely discourages the multiplication of youthful and independent types of leaders While it becomes more and more difficult for youth to gain experience of leadership and to demonstrate its capacity, the growing standardisation of life to which Dr Glover directs attention threatens to stifle such aspirations at the source Russia seems intent on producing citizens of a single type: Italy and Germany equally appear to discourage individuality and independence of mind, a shrewd

observer suggests that in the United States the object of education is to turn the human mind into a card index, and education in Great Britain is characterised by much the same standardisation and conformity to type. The danger of the breakdown of civilisation through sheer inability to maintain the quality of administration and consequent social equilibrium foreshadowed by Brook Adams in his "Theory of Social Revolution" is apparent alike in the democratic State or under dictatorship.

The contrast between this standardisation and mechanisation of life to-day and the glowing vitality of the Greeks which Dr Glover depicted so vividly is worth consideration. The challenge thrown down is fundamentally one of thought. If the adventurous, speculative mind, dynamic and eager for novelty, which the Greeks possessed, is one of the most essential factors for recovery of control over our specialised activities, the thrusting energy of our sectional and selfish interests, and to afford free access to everything in our rich heritage of civilisation which we have the capacity to enjoy, the most 'un-Greek' thing we can do, as Whitehead points out, is to copy the Greeks.

In the very suggestion of imitation or copying there is a hint as to our fundamental trouble. In an age of unprecedented change and technical advance, a tendency to take the Greek and Roman civilisation at its best as a standard, and to aim at reproducing the excellencies of these societies, is too static an ideal and neglects the whole range of opportunity. It is no longer sufficient to direct attention to the best that has been said and done in the ancient world. The result is static repression, and promotes a decadent habit of mind that can be traced in certain countries to-day.

Undue reliance upon the past for guidance and as a standard is a danger to any age. In this present age the peril is even more acute. The increasing *tempo* of technical development makes reliance on the wisdom of the past increasingly unsound. We are living in a period of human history when, probably for the first time, the assumption is false that each generation will live substantially amid the conditions governing the lives of its fathers, and will transmit those conditions to mould with equal force the lives of its children.

This fact alone would explain many of the difficulties in which we find ourselves, our persistent pursuit in economic and international affairs of mutually inconsistent policies. The shortened time-span of technological change increases the disturbance of social and economic life by the application of scientific discovery and in turn demands greater powers of adaptation and readiness to adopt new methods akin to these characteristic of the Greek. Our training must prepare the individual to face conditions for which the past is an imperfect guide. We require such an understanding of the present conditions as may give us some grasp of the novelty which is about to affect the immediate future.

We are here confronted with that divorce between wisdom and knowledge which is an untoward characteristic of many departments of political, industrial and social life. Despite known gaps in our knowledge of the social sciences, we have already vast stores of knowledge which could be utilised for the re-building of a social order capable of meeting the new conditions and making available for all the great resources with which now for the first time science has endowed mankind. Between that age of abundance for all, and the deprivations and distresses of the present time, stand the ideas inherited from a more static age in which available resources were incredibly smaller, and the routine in which those ideas have crystallised themselves. Routine, which should be the servant of society, is in a fair way to become its master.

It is fashionable at the present time to blame the machines for the mechanisation of life and the uniformity in working and in leisure hours imposed upon whole sections of the community. To do this is to make the fundamental mistake of regarding the machine as the master and not the servant of society, and to forget that the most regrettable results of industrialisation are for the most part not the direct fault of technology but of economic developments. As regards the technical and scientific aspects, in fact, our technical and industrial development was historically unavoidable. Mechanical power, as Mumford remarks in "Technics and Civilisation", is no new thing, but in earlier ages men had saner ideas of labour-saving devices, and the water mills of the first century B.C. were welcomed by Antipater of Thessalonica as a means of enjoying the fruits of Demeter without labour. The mechanisation of industrial and social life to-day is due essentially to our failure to understand the machine and to use it to serve and not to dominate the life of man. In our search for stability we have organised society to a point at which routine, upon which

civilisation is undoubtedly founded, becomes an obstacle to progress and adaptation to the new conditions

The absence of foresight in itself explains the lack of leadership Men seek security in the dull conformity to type Despite the many elements of scientific and sociological discipline required in the modern business mind, there is little of that power of general thought, undaunted by novelty, which is the gift of philosophy in its widest sense The absence of such a co-ordinating philosophy of life permeating the community spells decadence, boredom and the slackening of effort The mere compulsion of tradition has lost its force, or even may urge us into dangerous paths As Whitehead reminds us, our fundamental task is to re-create and re-enact a vision of the world, including these elements of reverence and order without which society lapses into riot, and penetrated through and through with unflinching rationality That is the challenge of the Greeks to our age, and whether we rise to the greatness of our opportunities, exploiting its adventure and mastering the network of relations which constitutes the very being of this epoch, or whether we collapse before the perplexities confronting us, depends both on our courage and our intellectual grasp

This challenge is unescapable. Advance or decadence are the only choices offered to mankind Perfection is essentially dynamic and not static Whether we are at present in a period of slow decline, or whether we are in a period of transition to a new form of civilisation involving in its dislocations a minimum of human misery, it would be rash to prophesy There are regions of human endeavour in which creative thought is still sufficiently active to inspire the hope that it may infect the more sterile regions of politics and sociology, where originality and constructive thought are so sorely needed The trend of discussions on the relation of science to social problems within the last two years justifies the belief that in this field thought has run ahead of realisation, and that only courage and vigour are required to secure the realisation of those dreams

The challenge presented to us so vividly alike by Dr Glover and Prof Whitehead is one to which the scientific worker above all should respond He is becoming increasingly conscious that, as the exploration of the physical world proceeds apace, the reaction of the new knowledge upon the social order, of which he himself forms a part, is opening up new fields of endeavour in which his method and impartial questioning spirit can find ample satisfaction He will remember that the great ages of the past have, on the whole, been the unstable ages the great achievements, the adventures of the past He will look back in a spirit of adventure, understanding the past, and look forward in the same adventurous spirit which unlocks the secret of the past, to the wide fields as yet largely untrodden, within which science may yet render its greatest services to mankind and make the rich resources of Nature available for all in a new social order worthy alike of the prodigality of Nature and of man's own rich intellectual heritage.

Reviews

Isomerism and Tautomerism

Tautomerism. By Dr. J. W. Baker (Twentieth-Century Chemistry Series) Pp viii+332. (London · George Routledge and Sons, Ltd, 1934) 25s net

THE term 'tautomerism' was introduced by van Laar in 1885 in order to describe those cases in which the compounds represented by two different structural formulæ are found to be "not isomeric but identical" A pioneer example of this phenomenon was discovered in benzene, since Kekulé, so long ago as 1870, was content to regard the single and double bonds in his formula as merely an instantaneous picture of a moving system, in which the double and single bonds were incessantly changing places. In this way he was able to account for the fact that the 1 . 2 and 1 : 6 di-derivatives of benzene are, as Laar expresses it, "not isomeric but identical" Kekulé's migrating bonds would now be described as a flow of valency electrons, and the phenomenon would perhaps be described as *electromerism*, but his fundamental ideas are still valid Indeed, at the present day, chemists would probably be unanimous in saying that *all* the diverse formulæ which have been assigned to benzene represent merely different aspects or phases of the same molecule, which they would not attempt to isolate

The examples cited by van Laar were, however, selected from a different range of compounds, namely, those in which a mobile hydrogen atom can occupy two alternative positions in the molecule Their interconversion—which is now usually described as *prototropy*—instead of involving a mere shifting of bonds or wandering of valency

electrons, calls for the displacement of a much more substantial atomic nucleus, and, although this nucleus is only a proton, it has not the same mobility as an electron. Almost as soon as van Laar's theory was announced, therefore, it was proved to be wrong by the isolation as independent chemical compounds of products which he postulated to be identical, but which in fact were entirely different in their physical, and even in some of their chemical, properties. Laar's own theory of tautomerism therefore died in infancy, even if it was not actually still-born; but, since the name which he invented has survived to form the subject of the present monograph half a century later, one may well ask how this has been achieved.

The answer is in some respects a simple one. The pairs of prototropic compounds, which Laar cited as examples of tautomerism, differ as widely as any other isomers in physical properties, such as colour, solubility, melting point, etc., and are distinguished from other isomers only in their ready interconversion. In particular, compounds of this type usually revert to an equilibrium mixture in presence of a mere trace of acid or alkali. They therefore give identical chemical reactions, except under special conditions, for example, in presence of a chemical reagent which has no strong catalytic properties or may even act as an anti-catalyst. At the meeting of the British Association in Oxford, the Chemical Section, under the presidency of Prof. J. F. Thorpe, recognised this point of view by adopting more or less unanimously the definition of tautomerism in the "Oxford Dictionary". This Oxford definition describes the phenomenon of tautomerism as follows:—"This term is applied to the property exhibited by certain compounds of behaving in different reactions as if they possessed two or more different constitutions; that is, as if the atoms of the same compound or group were arranged in two or more different ways, expressible by different structural formulæ."

This anonymous definition is purely chemical in character, since it is based exclusively upon the dual reactivity of a tautomeric compound, and is independent of the possibility of isolating the two 'phases' or 'forms' from which the two types of product are derived. This aspect is indeed so important that it is probable that no better selection could be made of a characteristic on which to base a *re*definition of the term in question. Others have, however, been attempted, since Kurt Meyer in 1913, and Schmidt in 1926, have proposed to limit the phenomenon to cases of prototropy, by insisting that the two sets of derivatives must be derived from two parent substances, which *differ from one another only in the position of a hydrogen atom and of one or more double bonds*. On the other hand, the author of the present monograph wishes to widen the term to include all examples of interconvertible isomers, and is bold enough to claim "universal acceptance" for the view that "*tautomerism is to be regarded as reversible isomeric change*."

The phenomenon of 'reversible isomeric change', which the reviewer has described as '*dynamic isomerism*', was discovered eight years before the appearance of Laar's paper, by Butlerow, who also recognised that it might proceed either with or without an added catalyst. His observations provide a valid explanation of the dual reactivity which Laar explained by an untenable theory; but chemists in general have never accepted the conclusion that Laar's term should be made to cover the whole range of the phenomenon discovered by Butlerow, and in practice there are many well-established cases of equilibrium between isomers which are generally excluded from the most inclusive of working definitions of tautomerism. Thus even the author of this monograph, in spite of his all-embracing definition, has nothing to say about isomeric changes in the benzene series, such as the conversion of hydrazobenzene into benzidene, or about the Beckmann change in the oximes, or about the combined bromination and reduction (by bromine and hydrogen bromide) which converts $\alpha\alpha'$ into $\alpha\beta$-dibromocamphor. General usage is, indeed, opposed to describing as tautomeric any isomers which only become interconvertible under special or drastic conditions, and which under normal conditions give no indications of the dual reactivity on which the Oxford definition is based.

The author's proposal to identify 'tautomerism' with 'dynamic isomerism' is a clear violation of the agreement reached at Oxford; but it has the advantage of enabling him to extend the scope of his book to include many topics which would otherwise have been excluded. Thus, in addition to the keto-enol change in the diketones and the facile isomeric changes which give rise to mutarotation, for example, in nitrocamphor and in the reducing sugars, he has been able to include as examples of the "three carbon system" some modern variants of Butlerow's interconversion of olefines, and to discuss a series of isomeric changes in the terpene series, where the conditions are equally severe. The book therefore provides a valuable guide to the widespread researches which have developed from J. F. Thorpe's work on glutaconic acid, as well as to much of the earlier and contemporary work on related subjects.

A theoretical basis for these researches is

provided in an early chapter on the "Modern Theory of Tautomeric Change" and by reprinting in an appendix a paper by Prof C K Ingold on the "Significance of Tautomerism and of the Reactions of Organic Compounds in the Electronic Theory of Organic Reactions", and the formulæ used in the text are accompanied by the curved arrows by which the theories in question are commonly expressed On the other hand, it may well be asked whether the author really believes in the 'bridge-bond', stretched to twice the normal length of a carbon-to-carbon bond, which he has included in one of his formulæ for anthracene (p 275), in defiance of the physical evidence as to the intolerable strain which such an extension must impose

The book is produced in an attractive form, with adequate subject and author indexes, and should have a wide circulation among chemists

Electron Physics

Einfuhrung in die Elektronik die Experimentalphysik des freien Elektrons im Lichte der klassischen Theorie und der Wellenmechanik Von Dr Otto Klemperer Pp xii + 303 (Berlin Julius Springer, 1933) 19 80 gold marks

PHYSICISTS have long felt the need of a book on electronic phenomena, in which experimental methods and results are collected together in a convenient form for reference Dr Klemperer has collected and sifted his material with great care and discrimination As a handbook for workers with electrons, his book will be an invaluable help A great number of useful tables and graphs are scattered throughout the work On p 12 we have a list of the formulæ, relationships and numerical values of the velocity and energy expressions for the electron, this is followed by a table, constructed from one given earlier by M G Fournier, containing numerical data for electrons of all velocities, and the curvature of their paths in different uniform magnetic fields From the last value given we see that if an electron moves very little less slowly than light, namely in the ratio 0 99999999870 to 1 (corresponding to a volt-velocity of 10^{10}), the mass increases to 19,585 its rest value

Details are given for obtaining electron beams of different kinds The varying types of information given by a Wilson cloud-chamber, and an ionisation chamber, a point counter and a Geiger-Muller tubular counter are clearly contrasted There is a very useful section on the photographic action of electrons and methods for comparing the intensity of electron beams photographically An account of electron diffraction is given in Chap v, which is entitled "The Electron as a Corpuscle and as a Wave" The calculations given in the book are of the simplest kind throughout A later chapter on the atomic electrons includes a very concise but reasonably complete description of atomic structure and spectroscopic notation (for one and more electron systems) Further subjects dealt with are photo-electric effect, thermionics, Compton effect, secondary electrons, ionisation in all its forms, interactions between free electrons and atoms, energy losses in collision, absorption of electrons and effective cross-section of atoms and molecules

The author discloses an intimate knowledge of these different fields and gives more than a thousand references to original papers There appear to be but few errors We note one in the small table at the top of page 3, and on page 150, Fig 97 for the results of Davis and Goucher's experiment is drawn too symmetrically about the x-axis The author deserves the thanks of all colleagues who are experimenting with electrons, whether fast or slow, and also of those who wish to have a complete summary of electronics for quick reference

Dialectical Materialism

(1) *Aspects of Dialectical Materialism* By H Levy, Ralph Fox, J D Bernal, John Macmurray, R Page Arnot, E F Carritt Pp vi+154 (London Watts and Co, 1934) 5s net

(2) *The Web of Thought and Action* By H Levy (The Library of Science and Culture) Pp vii+238 (London Watts and Co, 1934) 7s 6d net

(1) "THESE essays have arisen in response to an urgent demand that the philosophy guiding the practice of Modern Russia might be expounded in a form intelligible to the layman" A praiseworthy object indeed, since it is of the first importance that dialectical materialism should be lucidly expounded, then it will be possible to discuss the issues involved in the new philosophy, but few readers will get much enlightenment from this volume

Out of the six essays, the fifth, by Mr Bernal, alone attempts any general exposition It is written in a tone of strident dogmatism, take-or-leave-it style The exposition is anything but lucid, that this is not merely the judgment of a biased bourgeois reader may be gathered from the concluding essay by Mr Carritt The latter, who thinks that Marx would have found him a "hopeful convert", enumerates fifteen doctrines which he regards as "common to Mr Bernal and

himself" Then he goes on to explain his disagreements with Mr Bernal But we need not bother about these disagreements because there are in fact no agreements Mr Bernal, who is allowed a postscript, says that "the fifteen articles of Mr Carritt's cannot be said to be dialectical materialism, or even a part of dialectical materialism" He goes on to rub this in in a fashion that cannot be regarded as complimentary to the Oxford philosopher So the inquiring reader is likely to rise up from a perusal of the book somewhat bewildered

The four preceding essayists are more concerned with telling us about the impression made upon them by the new philosophy than by expounding it To Prof Macmurray, dialectical materialism is "a revolution in the conception of philosophy itself" It attracts him because "it is the one system of philosophy that recognizes the relation which necessarily exists between any philosophy whatever and the social conditions from which it arises". If this is a revolution or a revelation to philosophers, it is scarcely so to ordinary people, third-rate novelists a hundred years ago recognised that a man's philosophy was conditioned by his social status and tradition For the rest, Prof Macmurray is critical Thus there is no agreement about fundamentals between the contributors, what they do share is a dislike of "capitalism" "Capitalism must strive towards high prices and scarcity," says Prof Levy; and that of course reminds us of those recent and very successful capitalistic enterprises, Woolworths and Marks and Spencer

Prof Levy is the author not only of the first essay in this volume but also of the other book under review (2) The latter takes the form of conversations with "Mr Everyman", an engineer, a politician (Sir Herbert Samuel) and others Each conversation is followed by comments This form of literature seems to be getting popular, but to some readers it is tedious These conversations lack the interest of vivid reality in spite of the effort to impart it by a familiar and jocular tone, to be attractive they demand unusual imagination and literary skill, which are lacking here.

We are gradually led to the view that politics and history must be studied as sciences But many workers in these fields would reject this view and would maintain that our difficulties largely arise from the misapplication of the methods of the natural sciences to social studies. The historian and the sociologist do not participate in these discussions The "social historian" in these conversations is understood to have written a school textbook of physics, and his qualifications for expounding social studies are not apparent.

Problems of Crossing-Over

Handbuch der Vererbungswissenschaft Herausgegeben von E Baur und M Hartmann Lieferung 19 (Band 1) *Faktorenkoppelung und Faktorenaustausch* Von Curt Stern Pp vii + 331 (Berlin Gebruder Borntraeger, 1933) 54 gold marks

THE physical basis of crossing-over is now one of the major problems in genetics Its solution will require a more detailed correlation of genetical results with the behaviour of the pairing threads in meiosis than has yet been made The very extensive genetical facts already accumulated, and set forth at length in the book before us, call for a cytological explanation, but it is safe to say that all the theories hitherto put forward are defective either in supporting observations or in interpretation or in both Yet it appears that the problem has now reached a point where it can only be solved by the cytologists, with such further aid as genetics can give

This most intricate problem of cytogenetics clearly involves a fuller understanding of the structure and division of chromosomes and the relations of mitosis to meiosis, as well as the precise behaviour of the leptotene and zygotene threads The structure and division, as well as the behaviour of these threads, and the nature of the gene itself, are no less concerned in the solution of this problem It may be expected that much of cytology in the next decade will centre about these questions New methods of attack will have to be devised and new points of view developed

In the present work by Prof Stern, the abundant facts and theories of linkage and crossing-over are set forth *in extenso* While *Drosophila* supplies the largest single body of data, yet evidence of equal importance is furnished by many other plant and animal organisms, including *Zea*, *Lathyrus*, *Primula*, *Oenothera*, *Pisum*, *Apotettix*, and others Such phenomena as coincidence and interference in crossing-over and the linkage problems of three or more factors are discussed both theoretically and on the basis of the known results In the cytological aspect the views of Janssens, Belling, Darlington, Sax and others regarding the rôle of chiasmata are considered A short final section on interchromosomal linkage is devoted mainly to experimental cases in maize and *Drosophila*, with brief references to the well-known conditions encountered in *Datura* and *Oenothera*

This book, which has involved the author in much labour, will serve as a very useful storehouse of facts and a clearly arranged work of reference for future investigators. R. R. G.

Short Notices

Crystals and the Polarising Microscope a Handbook for Chemists and Others By Dr N H Hartshorne and A Stuart Pp viii+272 (London Edward Arnold and Co , 1934) 16*s* net

SECTIONS 1 and 2 of this book deal with crystal morphology. The information included in the fifty pages is surprisingly complete It is to be regretted, therefore, that the authors have not made use of the stereographic projection (space could have been found by deleting the recapitulations on pp 50 and 92) The use of etch-figures in, say, distinguishing between ortho- and clino-pinacoids and these in turn from prisms, might have added to the completeness of this portion of the book The text is liberally illustrated with clear diagrams (In Fig. 31, $1\bar{1}1$ should read $1\bar{1}0$ and on p 44, lines 6, 7 and 11 from top should be . 2{100} 4{101} and 6{$10\bar{1}1$})

It is difficult to refer to the optical treatment (Sections 3–6) without enthusiasm The ground covered would not be amiss in a volume of twice the size, and descriptions are throughout clear and concise The drawings, hereabouts, serve their purpose well, those of interference brushes, viewed through differently orientated sections, being particularly useful Some confusion may result from the authors' description of the mica plate It is the practice in Great Britain for quartz, mica and gypsum plates to be cut with the longer edge parallel to the ϵ or γ axis of the ellipsoid (Miers, Tutton, etc) In Sections 7 and 8, the authors make out a good case for the increased use of the polarisation microscope in industry and research

The printing is clear, and authors and publishers are to be congratulated on a book, useful alike to research physicists, geologists and crystallographers, as well as to chemists H E B

Sexual Life in Ancient Rome By Otto Kiefer Translated from "Kulturgeschichte Roms unter besonderer Berucksichtigung der Romischen Sitten" by Gilbert and Helen Highet Pp ix+379+16 plates. (London . George Routledge and Sons, Ltd , 1934) 25*s* net

IN matters relating to sex, the ancient Romans displayed the practical qualities which they brought to bear on all the problems of their lives, both public and private It affected their attitude generally to all forms of erotic emotion, as well as in the relation of the sexes For it has to be remembered that the ancient Romans, if not universally, very commonly, were indifferently homo- and heterosexual, and accepted that as a matter of course Dr. Kiefer, in the work of which this is a translation, has explored the records of the reactions of the Roman world in marriage, in religion, in literature and in art, and finds not only that there is little of the spiritualisation of this emotion such as existed among many of the Greeks, but also that there is in it no little of a sadistic element He is, however, by no means a supporter of the view which would ascribe the downfall of the Empire to decadent mores in relation to sex An acute analysis of the sexual element in the character of certain of the early emperors and members of their entourage, discounts the scandals of their biographers in some, but not all, instances

Satellite Station Tables By C M L Scott Pp vii+44 (London Edward Arnold and Co , 1934) 12*s* 6*d* net

IT sometimes happens in minor triangulation that well marked objects, which are otherwise suitable as trigonometrical points, cannot be observed from, though they are well placed for observing to' Burma, with its innumerable pagodas, offers thousands of examples of this, and it is not surprising that the book under review should have been written by the port surveyor at Rangoon These tables will save labour in cases in which there is much satellite-station work, though in ordinary minor triangulation, in which satellite stations are usually avoided, or are but rarely used, the surveyor may prefer to make his corrections by the application of elementary trigonometry

The tables have been carefully prepared and are well set out and printed. They are suitable for the purpose intended, which is, briefly, to reduce the angles taken at a satellite station to the values which they would have had if they had been observed at the inaccessible station itself The corrections are given to the nearest second, an accuracy more than sufficient for this class of work The book can be recommended to those who find themselves obliged to use satellite stations frequently The tables can, as remarked in the foreword, be made use of for tacheometrical calculations

Introduction to Modern Physics By Prof F K Richtmyer (International Series in Physics) Second edition Pp xviii+747+6 plates (New York and London McGraw-Hill Book Co , Inc., 1934) 30*s* net

THE first edition of Prof Richtmyer's book has been appreciated by so many physicists that the appearance of a second edition is bound to be warmly welcomed, and it is only necessary here to note the chief changes which have been made An adequate outline of the application of Fermi-Dirac statistics to problems in photo electricity has been added and the chapter on X-rays brought up to date The chapter on the structure of the nucleus has been considerably altered in view of recent work on artificial disintegration, and the neutron and positron both find a place, though perhaps a small one in the case of the latter. Two very important new chapters have been included, one on the vector model of the atom and one on the wave theory of matter The first will be particularly helpful to students, and the latter properly completes a first-class introduction to modern physics

A Large French Wind Tunnel

THE large wind tunnel which has just been completed at Chalais-Meudon is of considerable interest It is the second tunnel capable of testing a full-sized aeroplane to be constructed, the first being the 60 ft 30 ft tunnel at Langley Field, U S A , and it differs in one very important respect from any other wind tunnel, in that it is built in the open In general design it is not unlike the tunnel built by Eiffel in 1912 at Anteuil, a type now generally known by his name Air is drawn in through a contracting inlet and then passes as a parallel free jet across the observation chamber into a collector cone in which a gradual expansion takes place in order to recover most of the kinetic energy of the stream

In the older Eiffel tunnels, an airscrew or a centrifugal fan at the end of this expansion cone drew the air through the tunnel, which was itself housed in a large room through which the air returned to the intake end at a low speed As a single airscrew in the present large tunnel would be of such great diameter, the expansion cone has been allowed to discharge into a large chamber, or 'diffusor', from which the air is extracted by six airscrews, each working in a short expansion cone projecting from the back wall of the chamber The cross-section of the tunnel is everywhere elliptical, and at the working section is 52 ft wide and 26 ft high Each of the six airscrews is driven by a 1,000 h p variable speed electric motor, and a maximum wind speed of about 110 miles per hour is expected As mentioned above, an entirely novel feature is that the tunnel is in the open, instead of being housed in a building, thereby effecting a very large saving in the cost of construction

The new tunnel differs radically from the full-scale tunnel at Langley Field, which is of the return-flow type in which the air leaving the driving airscrew is guided by suitable ducts of gradually expanding cross-section back to the intake end of the tunnel, a type first successfully used by Prof Prandtl at Gottingen Such a tunnel is more costly than one of the French type, as there is at least twice as much ducting, but it has the advantage that the air in the tunnel is quite free from external atmospheric disturbances The power consumption for a given wind speed is less in the return flow type, but, if the figures given for the French tunnel are realised, the difference is not very great and may well be counterbalanced by the lower constructional cost

The one debatable point about the new tunnel is the advisability of placing such a tunnel in the open air, where the incoming air is subject to atmospheric disturbances There is very little data on the effect such disturbances will have in a large high-speed tunnel Some experiments made on a small model of a wind tunnel at the National Physical Laboratory many years ago showed that the disturbances in the tunnel stream were many times as great when the tunnel was in the open, even when the wind outdoors was only a light breeze, than when it was operated in the still air of a large room This model was, however, very small, and was only operated at the comparatively low speed of 40 ft /sec , at which the dynamic pressure is comparable with the pressure changes occurring in a gusty wind of quite low velocity In the French tunnel the speed is much higher, and moreover, the inlet and outlet ends are separated by many hundreds of feet, a dimension which may be large compared with the average extent of eddies in the atmosphere It may be mentioned that the tunnel has been placed in a hollow, with the view of shielding it so far as possible, but even with this protection it seems unlikely that it will prove possible to use the tunnel satisfactorily if any considerable natural wind is blowing It will be exceedingly interesting to learn how the tunnel behaves in this respect, and what is the limiting natural wind velocity at which the tunnel stream is still steady enough for normal measurements

A great deal might be written on the relative merits of the large tunnel capable of testing actual aircraft, and the alternative of testing scale-models in smaller tunnels, with guidance on scale-effect obtained by researches in a compressed air tunnel There is certainly one field in which the large tunnel should be exceedingly useful In these days the most marked tendency of aircraft design is towards the reduction of resistance and the attainment of high speed For investigations with this end in view, the large tunnel offers the great advantage that the actual aircraft can be tested with all its little imperfections, such as roughness of surface and unavoidable excrescences, and that the effect of practicable improvements in such details can be directly determined In testing small models in normal wind tunnels or in the compressed air tunnel, there is a distinct danger that the finer detail of the actual machine may not be properly represented

The large tunnel also holds out the possibility of testing the aircraft with its engine and airscrew running, and so of investigating the effect of attempts to reduce resistance without adversely affecting engine cooling This class of experiment, which is of great importance, is practically impossible on small models, though it can be carried

out in a smaller tunnel than the new French one The 20 ft tunnel in the United States and the new 24 ft tunnel at Farnborough were, in fact, built chiefly for such work The cost of running a full-scale tunnel, and of the preparation of machines for test therein, is necessarily heavy, and there is the limitation that even in such tunnels as those at Chalais-Meudon and Langley Field, only a small aeroplane can be tested The limit of span, without involving large corrections for the constraint of the limited stream, would probably be about 40 ft

In spite of such limitations—and every type of tunnel has limitations of some kind—the new equipment should prove of great value to the French in the study of aerodynamics, and it is to be hoped that results obtained by its use will be available to the world at large It is only by careful analysis and comparison of results obtained in various types of wind tunnel and on machines in flight that the greatest use can be made of the research work of the various institutions in different countries

Minute Intergenic Rearrangement as a Cause of Apparent 'Gene Mutation'

By H J MULLER, A PROKOFYEVA and D RAFFEL, Institute of Genetics, Academy of Sciences of the U S S R, Moscow

WHEN it was discovered that chromosome breakage and reattachment usually entail effects resembling those of gene mutations located at or very near the point of breakage, it was suggested, as one alternative interpretation of this phenomenon, that the change in position of genes near the breakage point, with respect to other genes in their immediate vicinity, might in itself be the cause of their altered mode of reaction upon the organism (Muller, 1930) This was an extension of the 'position effect' principle which had previously been proposed for the special case of the bar genes, two of which had been found to have a greater effect when in the same chromosome than when in opposite chromosomes (Sturtevant, 1925) Since 1930, numerous further illustrations have been found, by various investigators, showing the comparative regularity with which effects resembling those of gene mutations in nearby loci accompany breaks, but there has been little or nothing in their evidence that would serve to test the probability of the 'position effect' interpretation as opposed to the alternative conception that the disturbance involved in the process of breakage was of such a nature as to be likely simultaneously to upset and alter (once for all) the inner composition of genes in the vicinity The senior author has now, however, obtained definitive evidence (see Muller and Prokofyeva, 1934) of the correctness of the 'position effect' interpretation, through the finding that different rearrangements involving the scute locus in *Drosophila* in the great majority of cases result in phenotypically different 'allelomorphs', whereas nearly identical rearrangements (scute 4 and scute *L8*) have given sensibly the same 'allelomorphs'

The general question thus arises, what proportion of apparent mutations are only intergenic 'position effects' rather than autonomous intragenic changes? Of twenty-seven scute and achaete mutations investigated which have been produced by irradiation, it has so far been possible to demonstrate in eighteen cases that there was a breakage and re-attachment close to the scute or achaete locus Some or all of the remainder also are probably intergenic rearrangements, for it has been found in this investigation that the rearrangements tend to fall into two categories, gross and minute, the latter being of such a nature that a genetic discrimination between them and true intragenic mutations would be very difficult, or in many cases even impossible

One example of a minute rearrangement is scute 19, in which only a fraction of a single chromomere (or chromatin 'ring' number 2, as seen in the salivary gland) has, as shown both by genetic and cytological evidence (see Fig 1), become deleted, by a break on each side of it within the same chromomere, and inserted into another region of the chromatin (within the right arm of chromosome 2) We accept here Koltzoff's explanation of the structure of the salivary gland chromosomes, as bundles of practically uncoiled chromonemata the adjacent chromomeres of which form the 'rings' or 'discs' (see also Carnoy, 1884, and Alverdes, 1912, 1913), our work, however, shows definitely that the genes—usually more than one per chromomere—are contained within these chromomeres Special genetic and cytological methods explained elsewhere have shown that the displaced section of the chromomere here in question includes only about six (four to eight) genes This case does not illustrate a method of origination of recognisable 'deficiencies' alone If such a deficiency included but one or two genes, instead of six, it would in some cases be viable and resemble in its heredity an intragenic mutation, as other work of Muller (in press) has shown On the other hand, the inserted section, without the deficiency, could be mistaken for a simple genic 'suppressor', especially since, having been weakened in its activity by the effect of its changed

position, it could appear as a recessive (unlike most recessives, however, a duplication of the region in which it lay would not serve to counteract it) These changes might or might not be detectable cytologically, depending on their size If, finally, instead of having been lost or inserted into another region, the minute section dealt with in the case of scute 19 had only been inverted, while remaining otherwise in its place, the change would not only have behaved genetically like a gene mutation, but also it would have been impossible of recognition as a rearrangement, even by the new cytological method

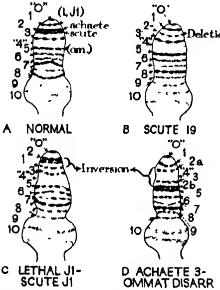

FIG 1 Appearance of extreme left end of *X*-chromosome of *Drosophila melanogaster* as seen in the salivary gland, in normal material and in the case of three minute rearrangements The exact or approximate () positions of the gene loci concerned are shown in the figure for the normal All four drawings are from typical specimens and show only the terminal twentieth ($\frac{1}{20}$) of the entire active region of the *X*-chromosome

The existence of minute inversions of the general type above mentioned was at first only an inference from the above and other cases of insertion, but soon actual proof of them was found The first case in point was that of scute J1 Here cytological examination (see Fig 1) proved that an only slightly larger section than the above, involving only two chromomeres or 'rings', 1 and 2, had become inverted (*in situ*) This was precisely the result which the senior author had been led to expect on the basis of this mutation having involved the simultaneous alteration of the effects of two nearby loci · those of lethal J1, normally to the left, as proved by genetic analysis of chromosome fragments broken between the two loci, and of scute, normally to the right The seeming 'double mutation' here, as probably in most other cases, was simply due to the two different position effects occurring at the two different (but nearby) points of breakage and reattachment

Another case in which the genetic expectation of a minute inversion, based on 'double mutation', was similarly confirmed by the cytological finding, was that of achaete 3 (= scute 10) Here the mutation other than that at the achaete locus was the ommatidial disarrangement 'om', which was proved to lie slightly to the right of achaete by the same method of analysis of fragments as that used before (analysis by crossing-over being virtually precluded in this as in the other two cases by reason of the small distances involved) In correspondence with this genetic situation, it was found that one point of breakage and reattachment lay within chromomere (= 'ring') 2, near the point in this chromomere where previous cytogenetic analysis by Muller and Prokofyeva (1934) had shown the achaete gene to be, while the other point of breakage and reattachment lay just to the left of or just within chromomere (= 'ring') 5, the region between these two points of breakage being exactly inverted (see Fig 1)

Since double breaks and reattachments are not all thus accompanied by a *discernible* position effect in two demonstrably separate loci, this genetic criterion of a minute rearrangement is only sometimes provided It is therefore evident that a minute inversion involving only a few genes (or sometimes only one gene ?) would often be not only cytologically but also genetically indistinguishable from an intragenic mutation, by any methods at present in use.

C A Offermann has directed our attention to the fact that there is evidence from another direction that a considerable proportion (if not all) of the apparent 'gene mutations' produced by X-rays are really the effects of changes in position caused by minute intergenic rearrangements. This evidence lies in the fact that the frequency of production by X-rays of readily demonstrable (gross) gene rearrangements is vastly greater in spermatozoa than in other cells, and that, corresponding with this, the frequency of production of apparent 'gene mutations' is also considerably raised in spermatozoa, as compared with other cells—although not nearly as much raised as is the gross rearrangement frequency (see Muller and Altenburg, 1930). Now exactly such relations are to be expected, if most of the induced 'gene mutations' are fine rearrangements, and if we accept the very probable hypothesis that rearrangements, like cross-overs, require contact between two chromonemata (or two portions of one chromonema) For the chromosomes are very much more crowded together and are more condensed in spermatozoa than in other cells. The much greater degree of crowding together would

give vastly more chance for juxtaposition of parts that ordinarily lie widely separated, and so would lead to a far higher frequency of gross rearrangements, while the greater degree of condensation would give more chance for contacts on the part of the very fine loopings that would be responsible for the minute rearrangements

As our studies of mutations in the X and other chromosomes have shown that apparent replicas of practically all known 'natural mutations' in *Drosophila* may also be obtained by X-rays, the further question is raised as to what proportion of 'natural mutations' in *Drosophila* may really be minute rearrangements This question is of moment because the range of possibilities of phenotypic change through intergenic rearrangements alone must be far from adequate for any indefinitely continued evolution The latter must depend for the most part upon intragenic change, and hence it is important for the study of evolution, though at present seemingly so impossible, to be able to distinguish some at least of the intragenic mutations from the minute intergenic types of rearrangement The matter acquires a greater urgency for geneticists when it is realised that they may now expect to have to meet attacks from orthogeneticists and Lamarckians, who may see in the present uncertainty regarding the 'building blocks of evolution', an opportunity of reintroducing teleological notions of evolutionary causation

In this connexion, it must not be forgotten that all the cytogenetic investigations of species-crossing have agreed in showing that species differences in general reside in chromosomal differences and are therefore fundamentally *Mendelian* in their inheritance When the chromosomes in species-crosses are able to undergo reduction, the species differences show spread of variation and eventual return to either parent species, whereas, when chromosome segregation is prevented—whether by asexual reproduction, by division of chromosomes at both maturation divisions (as in butterfly hybrids), or by the somatic origination of allotetraploidy—the hybrids breed true Now Mendelian differences have been found to originate only by a sudden process—mutation Since mutations involving intergenic changes are necessarily inadequate to provide most of the material for species divergence, it logically follows that a part of the mutations must be intragenic It is only to be expected that many of these would be similar, in their phenotypic consequences, to effects of intergenic origin, and that discrimination between the two classes of change would present considerable difficulties Such discrimination must, however, be eventually attempted

Obituary

Sir Horace Lamb, F.R.S.

HORACE LAMB was born at Stockport in 1849 His childhood was passed mostly in a household where the strictness of the religious ideas prevailing at that time left little scope for his naturally happy nature and his great vitality These qualities, which so endeared him to his friends in later years, began to appear at school At Stockport Grammar School, he had the good fortune to come under a sound and kindly scholar named Hamilton, who quickly appreciated his merits, and finally sent him up to Cambridge, where in 1867 he gained a classical scholarship at Queens' College. At that time his allegiance was almost equally divided between classics and mathematics, but his visit to Cambridge, when he sat for the scholarship examination, turned the scale in favour of mathematics. On his return to Stockport he decided not to take up his classical scholarship but to sit for a mathematical one at Trinity in the following year. His interest in classics and literature, however, remained with him all his life, and had a profound influence on his children, all but one of whom turned to literature or art rather than to science

The year of preparation for the mathematical scholarship was spent at Owen's College, Manchester, where, under Prof Barker, Lamb first experienced the recondite joys of the higher mathematics. At Trinity, which he entered in 1868, he graduated as second wrangler, and was elected to a fellowship At that time, and for some years afterwards, Cambridge mathematics was dominated by the tripos examinations A young man's ability was judged entirely by his place in the tripos, and his competence as a mathematician by the ingenuity of the questions which he set when in due course he appeared as a tripos examiner. Among the more old-fashioned, it was considered rather pushing to publish original mathematical work. The proper way in which a lecturer could make known any theorem which he might discover in his teaching was to set it as a tripos question The science of hydrodynamics was

at that time concerned almost entirely with an idealised, non-existent fluid which moved only in irrotational motion, without vorticity, and was thus well adapted for tripos questions

Lamb, in his first course of lectures on hydrodynamics, given at Trinity in 1874, broke new ground when he gave an account of Helmholtz's great work on vortex motion The substance of these lectures was published in 1878 as a "Treatise on the Motion of Fluids" This book, of some 250 pages, expanded in subsequent editions until as "Hydrodynamics" it covered some 700 pages During its long career, which is still in full vigour, it has become the foundation on which nearly all subsequent workers in hydrodynamics have built The long-continued supremacy of this book in a field where much development has been taking place is very remarkable, and is evidence of the complete mastery which its author retained over this subject throughout his life

It is of interest to notice through the various editions of "Hydrodynamics" the continually increasing stress which is laid on the physical side of hydrodynamics In the first edition (1879), the mathematical consequences of the conception of an ideal fluid are systematised and generalised in a form which is æsthetically very satisfying, and special problems are treated mostly as exercises of the type which occur in the tripos In subsequent editions, problems are treated more from the point of view of their intrinsic interest as illustrating natural phenomena or experimental conditions Numerical values are given for results which at first appeared only in symbolical form Motions such as turbulent flow, which even now defy exact mathematical treatment, are discussed, in the later editions, in the partial and incomplete forms which they had attained at the time of publication New developments have been brought into the scheme of the book, and it is this continuous growth as an organic whole that has enabled Lamb's "Hydrodynamics" to be still, after fifty-five years of life, the best book on the subject

In 1875, Lamb married Miss Elizabeth Foot, the youngest sister of the wife of his old headmaster, and shortly afterwards he went out to Australia, where he had been appointed the first professor of mathematics and physics in the new University of Adelaide Here he passed nine years, during which he established a laboratory and set the high tradition in science which Adelaide has preserved to this day. In spite of the cares of a large family, for three sons and three daughters were born while the Lamb family was in Australia, he published a remarkable series of papers on elastic and electric oscillations, and on hydrodynamics These were all characterised by great clearness of expression, and they established his reputation as an applied mathematician so quickly and firmly that, at the earliest opportunity, which occurred in 1884, he was called back to England to the mathematical chair at Owen's College At Manchester he threw himself into the work of the University and showed an aptitude for affairs which does not always accompany exceptional mathematical powers

In his early days, Lamb was very fond of mountaineering, and he spent several seasons in the Alps As soon as his children were old enough, he took them for long holidays walking in the Welsh hills or in Cumberland Later he took them in turns to Italy, where he soon acquired a considerable knowledge of Italian art

While in Manchester, Lamb spared no pains to make his lectures clear and well ordered The text-books which he published at that time bear witness to his care in that respect At the same time, he made a number of important contributions to applied mathematics The most noticeable characteristic of these works is the way in which the physical meaning of difficult analysis is clearly brought out One of the most striking of Lamb's works published at this time is the complete analysis which he made in 1904 of the waves produced in an elastic solid by an impulse of short duration He analysed the process by which a localised impulse can separate itself out into a number of disturbances of different types which travel at different speeds and therefore become separated The seismological implications of this work have scarcely yet been fully discussed Among other geophysical problems are the effect of vertical loading on the earth's surface (1917) and the waves in an atmosphere the temperature of which decreases with height (1910) This last paper must form the basis of any future attempt that may be made to calculate the tides in the atmosphere

In 1920, Lamb retired from Manchester, and shortly afterwards returned to Cambridge, where his friend and colleague Lord Rutherford had just become the professor of physics Trinity College made him an honorary fellow and he very frequently dined in hall, where his youthful nature made him very welcome to a company which included men nearly fifty years younger than himself

At this time, Lamb's mind was much occupied with problems of aeronautical research Until a few years ago, he was a member of the Aeronautical Research Committee, and when he retired from that body he still kept in touch with the more purely scientific side of its activities Sometimes he helped with constructive criticism, sometimes he formulated aeronautical problems in a mathematical form, and sometimes he gave definite solutions of problems formulated by others His services in this field were very much appreciated by those responsible for directing aeronautical research in Great Britain, and nowhere is his loss felt more deeply than among those whom he honoured by his kindly but telling criticism of their work

In 1884, Lamb was elected to the Royal Society He served three times on its Council and was twice a vice-president In 1931, he was knighted He was president of the British Association in 1925–26 and of its Section A in 1904 He died on December 4

Lamb had three sons and four daughters. His eldest son, E H Lamb, is professor of engineering at Queen Mary College, London The second, W. R. M Lamb, is secretary of the Royal Academy and was formerly a fellow of Trinity The youngest is Henry Lamb, an artist. One of his daughters is

Mrs Palmer, now fellow and tutor of Newnham College, Cambridge Another is Lady Brooke, wife of Sir J R Brooke, of the Electricity Commission

This record of Sir Horace Lamb would be incomplete without referring to his sunny temperament and the vivid interest in every kind of human activity, which made him so fascinating a personality to all who had the good fortune to come into contact with him G I T

Dr A A Belopolsky

Aristarch Apollonovitch Belopolsky, the well-known astrophysicist, member of the Russian Academy of Sciences since 1903, honorary director of the Pulkovo Astronomical Observatory in the U S S R and since 1910 an associate of the Royal Astronomical Society in London, passed away at Pulkovo on May 16, 1934, at the age of eighty years

The main work of Belopolsky's long and laborious life was connected with spectroscopic investigations of the sun and stars It was he who was charged in 1891 by F A. Bredichine, then director of the Pulkovo Observatory, with planning the astrophysical equipment for use with the 30-in refractor, visual at first and later for photographic records. His first observations were on Nova Aurigæ, in 1892, and since he never missed any new star, he accumulated a series of valuable spectrograms and obtained in some cases pure absorption spectra characteristic of the very first stages of the outbursts At the same time, he made spectroscopic observations of the sun and was to the last president of the Solar Committee in the U S S R He was the first to determine, in 1915, the temperature of sunspots from his spectrograms

In 1912 the Russian Academy of Sciences placed an order with the firm of Sir Howard Grubb, then in Dublin, for a big Littrow spectrograph, of 7-metre focal distance and a dispersion in the third order of 1 mm = 0 76 A Owing to the War and succeeding adverse circumstances, the instrument did not reach Pulkovo until 1923, and Belopolsky immediately took up his part of the international research on the solar rotation.

Many beautiful records and classical discoveries testify to the knowledge and the experimental skill of Belopolsky Thus, in 1894, he discovered the velocity variations of δ Cephei associated with the changes of light Two years later he made the same discovery for η Aquilæ and in 1899 for ζ Geminorum. In 1895 he confirmed Keeler's discovery of the rotation law of the rings of Saturn From his examination of the spectra of γ Virginis and γ Leonis he made an important advance in the determination of the parallaxes of double stars His favourite star, however, was Polaris, and every second year he took up the determination of its elements A very striking achievement was his experimental proof of the Doppler effect. Already in 1894 he had set up a device consisting of a series of rapidly rotating mirrors opposed to each other, thus making it possible to get very high speeds of the reflected ray of light In 1898 the arrangement was ready and Belopolsky was able to confirm by a purely laboratory experiment a fundamental law of modern astrophysics

To understand this remarkable gift in the application of physics to astronomy we have to go back to Belopolsky's education His parents were well educated but poor, and they encouraged his intellectual ambitions The boy revelled in natural sciences, made experiments at home in physics and chemistry, and was a craftsman, achieving good results with the simplest means and making instruments practically out of nothing He studied at the University of Moscow and graduated in 1877. F A Bredichine was then at the head of the Moscow Observatory, he at once appreciated the gifts of the young man and made him his assistant In 1888 Belopolsky went to the Pulkovo Observatory, where he stayed for the remainder of his life He published his work on sunspots and their movement in 1886 From the beginning of the *Astrophysical Journal* in 1895, he took a great interest in the periodical and was one of its associate editors

During his career at the University of Moscow, Belopolsky had to provide for himself and knew what hardship meant But science had captured him and he never failed her, whether in good or in hard times He was a very kind-hearted man, with a real sense of justice and truth.

Rev T E Espin

We regret to record the death on December 2 of the Rev T H E C. Espin, the well known amateur astronomer He began observing with a 1 in telescope while at school at Haileybury, where his interest in the heavens was aroused by the appearance of Coggia's comet in 1872, and by his form master's lectures on his favourite hobby, astronomy

On proceeding to Oxford, where he took his degree in 1881, Espin found his first double star with a 3-in refractor, and evinced such enthusiasm that the Savilian professor allowed him the use of the University 13 in At the age of twenty years he was elected a fellow of the Royal Astronomical Society, and soon afterwards was appointed special observer to the Liverpool Astronomical Society, of which he was a founder and president At West Kirby, Wallasey and Wolsingham, where he was curate (1881–88) to his father, Chancellor Espin, a well-known ecclesiastical lawyer, he astonished the astronomical world by a survey of red stars, with a large reflecting telescope, of the whole of the northern heavens, he found 3,800, a total unequalled by any other observer During this research more than thirty variables were discovered and observed until their range and period were determined They included several remarkable objects, notably X Ophiuchi, V Cassiopeiae and R Canum Venat At the same time he almost doubled the known number of type IV stars In 1899 Mr Espin began a micrometrical examination of all stars shown on Argelander's charts—a total of well over 300,000—for new double stars, and before his death had found 2,575 For these researches, extending over forty years, and for the discovery of Nova Lacertae, he received the

Jackson-Gwilt medal of the Royal Astronomical Society.

Mr. Espin invented a spectroscope, a variable-power eyepiece and Espin's star detector. On Röntgen's discovery of X rays, he built several high tension machines, culminating in a huge 24-plate Wimshurst, with which for many years he treated invalids from all over the country. In recent years, with the collaboration of W. Milburn, his astronomical assistant, he investigated the radioactivity of local spring waters and published the results in his observatory circular for 1933.

During the later years of his life, when he was unable to spend long hours in the observatory, Espin made and examined rock sections from his specimens collected abroad, especially of those from Vesuvius, Etna and Les Puys de Dôme. His scientific interests were thus very wide, and he brought both observation and thought to bear on many objects upon the earth as well as in the heavens. There are now few natural philosophers of his type, and his death has deprived the world of one who contributed much to its knowledge.

MR. ERNEST BINFIELD HAVELL, whose death at the age of seventy-three years occurred on December 30, was well known as one of the foremost authorities on Indian art, architecture and technology. He first went to India as superintendent of the Madras School of Art, and in 1896 was transferred to the Calcutta School, retiring from the Education Service in 1908. While at Calcutta he founded what has since come to be known as the Calcutta school of painting, and it was largely owing to his interest in indigenous industries that the village hand-loom industry was revived. An intense and enthusiastic appreciation of the aims of Indian art, especially of the Mogul and Rajput schools, was the basis of his conviction that the only future possible for a living school of art in India lay in an evolutionary development of the indigenous art, free from the influence of European ideals and methods. The enthusiastic welcome and support his views received from the Nationalist party in India proved an embarrassment rather than an assistance when, after his retirement, he endeavoured to promote in England a better understanding of India's artistic achievement. Mr. Havell was a voluminous writer on Indian art and technology, his best known work being a "Handbook of Indian Art" (1920).

WE regret to announce the following deaths:

Mr. H. G. Ponting, the official photographer to the Scott Expedition of 1910–13 to the South Pole, on February 7, aged sixty-four years.

Prof. Arthur Thomson, emeritus Dr. Lee's professor of anatomy in the University of Oxford, president of the Anatomical Society of Great Britain and Ireland in 1906, on February 7, aged seventy-six years.

News and Views

Ethnographical Films

CONSIDERABLE interest has been aroused by a recent announcement that the Trustees of the British Museum have accepted the donation of a cinematograph film of the life of the Worora tribe of the Kimberley district of north-west Australia. The film was presented by Mr. H. R. Balfour of Melbourne. It was taken on the Government Native Reserve of Kunmunya, and shows the present conditions of native life. Technological processes, such as the making of stone axes and spear heads, in which these people are specially skilled, the making of fire by twirling one stick on another, the spinning of human hair for thread and the like are shown as living crafts. The 'shots' also include ceremonies and dances and an emu corroboree. The film has already been shown to missionaries, learned societies and medical students in Australia; but as is explained by Sir George Hill in a letter to *The Times* of February 7, owing to the fact that it was taken on a Government reserve, under the regulations of the Commonwealth Government, it cannot be shown commercially. With the permission of the Trustees of the Museum, arrangements have been made for the film to be shown at a meeting of the Royal Anthropological Institute to be held on March 19 at the London School of Hygiene and Tropical Medicine, but only fellows of the Institute and their guests can be admitted. A description of the film has been supplied by the Rev. J. R. B. Love, who is superintendent of the reserve and is well acquainted with the language of the Worora.

ALTHOUGH this film will, no doubt, prove of the greatest interest as an ethnographical record, it is by no means unique. The cinematograph camera has long been used as an adjunct to ethnographical exploration. One of the earliest records of this kind was the series taken by Prof. C. G. Seligman when a member of the Cooke Daniels–Seligman expedition to New Guinea thirty years ago, which was shown at the Leicester meeting of the British Association in 1907; and the late Sir Baldwin Spencer showed a detailed record of the life and corroborees of the natives of northern Australia at a meeting of the Royal Anthropological Institute in 1914. The diffidence felt by the Trustees of the British Museum in accepting the gift, notwithstanding the fact that it was a 'non-flam' film, has directed attention to the fact that the British Museum possesses one other film only, and that there is no official collection in Britain of these extremely valuable records of the life of primitive peoples, now rapidly passing away.

THE possibility of forming such a collection or repository was one of a number of points connected with the making, selection and preservation of cinematograph films of anthropological and ethnographical

interest, which was referred to a special committee appointed by the recent International Congress of Anthropological Sciences held in London in August last The committee is international in its composition, Great Britain being represented by Capt T A Joyce of the British Museum The matter, however, is not to be allowed to rest there so far as Great Britain is concerned, and it is announced in the February issue of *Man* that the British Film Institute has established a Scientific Research Panel of its Advisory Council, of which Prof J L Myres will act as chairman, to collect information as to the extent to which the cinematograph has been used in scientific work, details of methods and difficulties in technique, and particulars of films of scientific interest which have not been put into circulation through the ordinary commercial channels The Panel will welcome information on any of these points, communications should be addressed to the Secretary, British Film Institute, 4 Great Russell Street, London, W 1

City and Guilds (Engineering) College, London

IN speaking, at the jubilee celebration of the City and Guilds (Engineering) College, Prof H E Armstrong directed special attention to the origin of the Imperial College, tracing this and the general development of scientific activity at South Kensington mainly back to the late Lord Playfair, in particular to his appointment at the Museum of Practical Geology, the home of the Geological Survey, about 1843 South Kensington, he believes, is still without any memorial of the great 'little' man Discussing the history of the Royal College of Chemistry, established in Oxford Street in 1845, now the Royal College of Science, Prof Armstrong said that the funds were chiefly obtained from the farming community, owing to the enthusiasm aroused by Liebig in his tour throughout agricultural England in 1842–43 When the Royal College of Science was opened, its rural promoters had looked forward to the development of the school in the interests of agriculture Man may propose but professors dispose nothing was further from Hofmann's genius Agricultural chemistry, Prof Armstrong said, is not taught in England in a way in the least comparable with that in which engineering has been taught in the Guilds Colleges. He ventured to express the hope that, by the time the College of Chemistry celebrated its centenary, it will have learnt what its original purpose was and will seek to fulfil this By that time perhaps the world will have recognised that no other subject is so worthy of chief attention as is agriculture

SPEAKING of his work at the Central, after referring to the importance attached both there and at the Finsbury College to engineering as a necessary subject in the chemist's course, Prof. Armstrong said of the engineer: "I made no attempt to teach him chemistry: that I soon found to be impossible. I tried to teach him through simple acts of chemical inquiry, to experiment with a purpose, to observe accurately. above all to describe his work in lucid English: to take notes, in short, the hardest task of all My schoolmastering was not popular with many, at the time In after years I have had my full reward, as not a few have told me that my insistence on their learning to help themselves has been of special value to them" He ended by saying "At this, perhaps the most critical and solemn moment of my life, in the interests of our national engineering efficiency, I would plead for the recovery of the original spirit and a reconstitution of the College as a separate entity"

Sir Alfred Ewing and Seismometry

DR C DAVISON writes "During the five years (1878–83) that Ewing spent in Japan, like other English teachers in Tokyo he was infected by the enthusiasm of Prof John Milne, and became one of the first members, and afterwards a vice-president, of the Seismological Society of Japan founded by Milne in 1880 At one of the early meetings of the Society in that year, Ewing described his seismograph for horizontal motion, in which he preceded Rebeur Paschwitz in devising a horizontal pendulum with two fixed supports In 1881, he followed with an account of a seismometer for vertical motion, this, with the preceding, forming the well known instrument made by the Cambridge Instrument Co, Ltd In the following year, he devised his duplex pendulum seismometer The horizontal pendulum was erected in the Engineering Laboratory of the University of Tokyo in November 1880, and, at several later meetings of the Seismological Society, he exhibited the diagrams obtained with it The interest aroused by these early accurate records of the movements of the ground during an earthquake can be readily imagined Shortly before he left Japan, Ewing wrote his great memoir on 'Earthquake Measurement', in which he described the various forms of known seismographs and their underlying principles (*Tokyo Univ Sci Dept Mems*, No 9, 1883) Soon after this, his active interest in seismometry seems to have ceased, for, after his return to Great Britain, he made only one new contribution, that on seismometric measurements of the vibrations of the Tay Bridge during the passing of railway trains (*Roy Soc Proc*, **44**, 394–402, 1888) In these experiments made with a duplex pendulum seismometer, he showed that the greatest lateral and longitudinal movements of the bridge were about $\frac{1}{16}$ in and $\frac{1}{40}$ in respectively"

Research Laboratory at the National Gallery

TOWARDS the end of 1934, the Trustees of the National Gallery approved a scheme for the establishment of a laboratory to undertake the physical examination of pictures by means of X-rays, ultra violet and infra-red radiations, and by micrographic methods They also appointed a committee, consisting of Sir Henry Lyons, Sir William Bragg, and Dr. H J. Plenderleith, to act as an advisory body, should need arise: the laboratory is in charge of Mr. F. I. G Rawlins A considerable amount of the plant has already been installed, and work has begun with photomicrographic investigations, and to some extent with ultra-violet light. At the present rate of progress

it is expected that the laboratory will be fully equipped by the end of April The X-ray apparatus will contain several novel features. In addition, a number of ancillary researches are being initiated, including the microscopical examination of woods used for panels it is hoped that this inquiry will produce valuable data for making the description of works in future editions of the catalogue more exact, as well as being a help in the question of attribution

Large Sunspot Group

A MODERATELY large sunspot group which formed on February 5 has attracted, for its size, an undue amount of notice in the daily Press The group occupies about 800 millionths of the sun's hemisphere, and a spot of these dimensions will be no uncommon occurrence during the next six or seven years, as the sunspot cycle passes through its maximum in 1938 Actually, a larger group, occupying 1000 millionths of the sun's hemisphere, has already appeared since the last minimum in 1933 This group had its central meridian passage on April 21 9, 1934 (see the *Observatory* for February 1935, where an account of 1934 sunspot activities will be found) The present spot is, however, not without interest No spot was detected on a photograph exposed at Greenwich on February 5 at 10^h, but at 11^h a spectroscopic disturbance was *seen* in the spectrohelioscope, which seems to have been the genesis of the actual spot On account of cloud, no photoheliogram was taken on February 6, and the spot appeared fully developed on February 7. The spot's latitude is 14° S , and it was born west of the central meridian Its central meridian passage—if it survives—will take place on March 14 next The spot is of such a size that it could just be seen by the naked eye if it was on the central meridian Near the limb, where the spot appears foreshortened, a spot of this size would be invisible It is interesting to note that the number of naked eye sunspots per annum follows the ordinary sunspot curve very closely, and that the 11-year cycle could well have been discovered by an observer provided only with a smoked glass— and a good climate

Natural and Artificial Clouds

IN his Friday evening discourse at the Royal Institution on February 8, Sir Gilbert Walker discussed natural and artificial clouds Apart from cumulus clouds of various types, the causes of the geometrical patterns that are to be seen in the sky must be sought in the behaviour of layers of fluid which are made unstable either by heating them from below or cooling them from above. It has been known for fifteen years that a stationary liquid when unstable develops a polygonal pattern, and that an unstable liquid flowing down a trough forms pairs of vortices rotating in opposite directions, with their axes parallel to the direction of flow, or of shear. Sir Gilbert's pupils have carried these investigations further, and A Graham used a wind tunnel formed with a heated iron plate as lower surface ; its upper surface was a cool glass strip 8 ft long and 9 in wide, a third of an inch above the iron plate When pulled by a motor, this gave variable rates of shear in the air. The former explanation of clouds occurring in long rolls or in a rectangular pattern as caused by Helmholtz waves was shown to be unsatisfactory , and it was verified that while a rapid shear due to motion exceeding one inch a second produces longitudinal cells, one less than a fifth of that rate leads to transverse cells, and an intermediate rate to a rectangular pattern Various types of longitudinal clouds were discussed, and Sir Gilbert withdrew his former explanation of spirals in these clouds as due to stream lines, showing that there are normally two equidistant spirals like those in a twistdrill, and that these appear to be the two component vortices intertwined Photographs of clouds were used to demonstrate the formation of a number of patterns of clouds at different heights , and an account was given of the explanation suggested by A Graham of the paradox that, in the laboratory, liquid rises in the axis of a cell while in air there is descent there Attention was also directed to the existence of clouds due to instability or the sun , and to the use of clouds of longitudinal and rectangular patterns for long-distance gliding under the name of 'cloud-streets'

Structure of the Universe

SPEAKING to the Durham University Philosophical Society on February 1 at Armstrong College, Newcastle-upon-Tyne, Dr Herbert Dingle, assistant professor of astrophysics at the Imperial College of Science and Technology, gave a historical account of the development of our ideas of the structure of the universe. Defining the 'universe' as the whole of physical existence, he pointed out that this apparently general subject demands a treatment which is in many respects unique The idea of infinity became general with the Renaissance, and this seemed to place the conception of the whole universe beyond the power of the finite mind, until Newton restored the possibility with his implicit concept of universal law which was everywhere applicable. There have been two criticisms of this , a valid objection, that this extension of locally derived law may be incorrect , and an invalid one, based on our imperfect knowledge of atomic processes, which ignores the fact that the laws of a whole can be arrived at without combining the laws of elementary parts. Towards the end of last century, it was argued that the Newtonian law of gravitation was inconsistent with an infinite extension of uniformly distributed matter, of however low a density Relativity theory, however, made such homogeneity acceptable. The Einstein, de Sitter and expanding universes are widely known nowadays, but Dr. Dingle made it clear that there is nothing esoteric about such theories, and that their underlying principles might have been expected from recent observations even if they had not been discovered when they were. It was stated also that there is no objection to belief in an infinite space, if one is willing to admit that in Einstein's space-time it may be quite beyond physical exploration.

The Uncertainty Principle

In a lecture delivered to the Physical and Chemical Society of University College, Nottingham, on February 4, Prof. E Schrödinger directed attention to the difficulties and contradictions which arise from attempts to unite quantum theory with geometry and with the theory of relativity Although the first researches on wave mechanics used the relativity ideas, they are really in flat contradiction to them. The theory of relativity supposes that rods and clocks can be used to measure exact lengths and times, and that in some way velocities can also be measured accurately Unfortunately, Heisenberg's uncertainty principle, which appears to be inherent in quantum mechanics, lays down that simultaneous accurate measurements of position and velocity are impossible Moreover, the regulation of a clock is not possible to more than a limited degree of accuracy, except when the clock is infinitely heavy Similar considerations forbid us to apply our ideas of Euclidean geometry, based upon ideal rigid measuring rods, to small physical regions Physicists have at least as much confidence in the special theory of relativity as in quantum theory, the problem of devising a unified theory appears to be still unsolved.

A French Chemical News Service

We have before us the first number of *Les Nouvelles de la Chimie*—a new monthly paper issued in Paris. It resembles in its general appearance a daily paper, a fact which may seem unusual in England, in France there exist already several medical news journals having the same format The front page of the new journal contains news items, interviews and similar topical material, on the second page we find a review of general scientific activities in the universities and laboratories, while the third and fourth pages are devoted to general technical and economic information The editor of the new paper is M Jean Gérard, the active director of the Maison de la Chimie and its Centre of Documentation We understand that if the new venture fulfils the expectations of its promoters, it will develop into a weekly and finally into a daily news service covering not only the field of chemistry but also that of science in general.

Baffin Island Survey

The annual report of the Canadian Department of Marine for the fiscal year 1933-34 contains some interesting information respecting the operations of the Canadian Hydrographic Service during the period under review. Among other technical observations, the Service carried out a survey of the Baffin Island coast, of which the following extract is a partial description. "In aspect, the south-eastern coast of Baffin Island is very bleak, bare rugged hills of gneiss and granite rising to elevations about 600 feet close to the sea and to greater heights inland The ragged shore is broken by numerous fiord-like inlets, but from Pritzler Harbour to Barrier Inlet, 45 miles north-northwestward, the shore is fronted by many islets, rocks and shoals of a most dangerous character The 50 fathoms contour, which lies at an average distance of 3 miles off the islands, should be considered the danger line The country is quite uninhabited except for some Eskimos who travel gregariously along the coast in whaleboats (omiaks) These natives appear to be of a very good type—healthy, honest and well adapted to the rigours of the country Their habitat is both the north and south coasts of the long peninsula which separates Frobisher bay from Hudson strait The small, swift rivers which flow into the heads of the inlets are well stocked with a fine species of salmon trout weighing up to 8 lbs, this food, together with seal, constitutes their chief diet At certain times a caribou hunt takes place and the hunters travel inland for several days to secure fresh meat In addition, the country also provides aquatic fowl, ptarmigan, arctic hare and an occasional walrus or polar bear"

Reversing Falls at Barrier Inlet

After recording the absence of good ship harbourage between Pritzler Harbour and Barrier Inlet, the report of the Canadian Department of Marine goes on to describe the physical features of the latter, which is an arm of the sea extending 12 miles inland At the entrance, it has a width of about a mile and a half, but two miles inside, the width contracts to three quarters of a mile The channel is still further constricted at this point by a number of rocky islets, connected at low stages of the tide and leaving only two narrow passage-ways less than a hundred yards wide "The free flow of the tide in and out of the inlet being thus constricted at the narrows, a 'head' of water is formed and creates a reversing falls At the time of low tide on October 1, there was a sheer outward waterfall $8\frac{1}{2}$ feet in height, and the lowering of the fiordal waters continued for a space of $2\frac{1}{2}$ hours whilst the tide was rising outside at the foot of the cataract Slack water occurred for a few moments when the flood tide reached the elevation of the water in the fiord but almost immediately the inward rush of water formed whirl pools and great eddies and soon waves, 6 feet high, careened wildly from side to side A boat attempting to pass through at such time would be engulfed"

American Museum of Natural History: New Director

According to *Science* of January 15, Dr George H. Sherwood has resigned his post as director of the American Museum of Natural History to give his entire time to the School Service Section as curator-in-chief of education Dr Sherwood will remain honorary director of the museum Dr Roy Chapman Andrews will succeed Dr. Sherwood as the active head of the museum As leader of the Central Asiatic Expeditions of the American Museum of Natural History, Dr Andrews took his first expedition into the field in 1916 to work in the territory of Tibet, South-west China and Burma His second expedition went into North China and Outer Mongolia in 1919, and the third expedition has worked in Central Asia, especially in Mongolia, since 1921,

where it uncovered some of the richest fossil fields in the world Dr Andrews was awarded the Elisha Kent Kane Gold Medal of the Philadelphia Geographical Society, previously given to only eight explorers Brown University and Beloit College have both conferred on him the degree of honorary doctor of science He has been given the Hubbard Medal of the National Geographic Society in recognition of his discoveries in Asia He is well known as a lecturer and author of popular books and articles on the results of his various expeditions, including a large volume covering his entire field work in Mongolia and China up to the present time entitled "The New Conquest of Central Asia"

Organisation of Museums

THE Madrid Conference on Museography on October 28–November 1, 1934, attended by seventy five experts representing twenty different countries, was noteworthy for the publicity it gave to the organic life led by museums outside their actual exhibition galleries, quite as much as for the success of the Conference in paving the way for a general treatise on the principles and practice of museums The main object of this Conference, organised by the International Museums Office and the International Institute of Intellectual Co operation, was to collect observations and the results of actual experience from as large a number of museums and countries as possible, rather than the formulation of general rules The agenda of the Conference included discussions on the general principles of the architecture of a museum, on museum equipment both in exhibition and other public rooms and in the museum services, on lighting, heating, ventilation and air-conditioning, the conversion of ancient monuments and other buildings into museums, general principles regarding the enhancement of works of art; methods of presenting collections, organisation of stores, reserves and study collections, permanent and temporary exhibitions, problems arising from the growth of collections, exhibition material, plans of rooms and the numbering and labelling of exhibits A number of special questions such as collections of sculpture, decorative and industrial art, folk-art and ethnography, and graphic and numismatic collections were also discussed The Academy of Fine Arts, Madrid, was specially fitted up for the Conference by the Spanish Government, and the International Museums Office lent a considerable amount of graphic and photographic documents to illustrate the papers

Electric Discharge Lamps for Road Lighting

IN many of the long stretches of main roads between towns and villages the only practical way of lighting at present seems to be by means of the lamps on the vehicles In a paper on "Electric Discharge Lamps and Road Lighting" read to the Institution of Automobile Engineers on December 11, Mr. H. Warren and Mr L J Davies show how the length of the permanent illumination of roads can be extended, with acceptable economy, by means of the new discharge lamps, when care is taken to distribute the light scientifically by means of suitable lanterns Controlling the reflective properties of the road surfaces has also to be taken into consideration With mercury and sodium vapours we have two substances which, when excited in the correct way, produce a sufficient proportion of energy in the visible spectrum to give a two- or three-fold increase in efficiency over incandescent lamps A fifty fold efficiency is theoretically possible, but the practical utilisation of electrical discharges has just made a beginning At present, electric discharge lamps for street lighting are of two main types, high-pressure mercury vapour and sodium vapour The former type of lamp is most favoured in Great Britain, while on the Continent and in America the sodium vapour lamp is most used Mercury discharge lamps have an excellent 'luminous output' during their lives, which are longer than those of other forms of lamp The colour of the lamp, when viewed directly, is greenish-white In the colours radiated, blue, green and yellow predominate, but red is practically lacking By incorporating cadmium with the mercury a satisfactory red tinge can be introduced, but at a slightly lower efficiency The colour correction of these lamps is receiving a great deal of attention in commercial research laboratories at present

Continuously Evacuated Radio Transmitting Valves

AT the meeting of the Wireless Section of the Institution of Electrical Engineers on February 6, a paper entitled "Continuously Evacuated Valves and their Associated Equipment" was read by Mr C R Burch and Dr C Sykes This paper describes the development of demountable thermionic transmitting valves of various power ratings, the valves being evacuated continuously by means of oil condensation pumps This work has arisen out of some experiments carried out in 1929 on the distillation of lubricating oil in a molecular still It was found that one of the fractions was about a thousand times less volatile than mercury, so that if such a liquid could be used as the working fluid in a condensation pump, a vacuum of the order of 10^{-6} mm should be attainable without the use of liquid air or other refrigerants, and such a vacuum is quite adequate for valve exhaustion These expectations have been fully realised in the development of oil-condensation pumps which will work against a fore-vacuum of 0·05 mm and will produce a vacuum of 10^{-5}-10^{-6} mm at a speed of 20 litres per second Such pumping equipment is described in the paper in some detail, and reference is made to its application to the production of thermionic valves of a power rating ranging from 20 kw. to 500 kw. for high-frequency furnaces and for radio transmitting stations Several valves of the 30 kw order have been in use on commercial radio traffic at the Post Office station at Rugby for long periods, and they have given satisfactory service A 500 kw. valve is in the stage of experimental trial on the long-wave transmitter at Rugby. The relative merits of these valves and those of the sealed-off type were discussed

briefly in the paper, and were enlarged upon by several speakers in the discussion which followed the reading of the paper

Deep-Sea Observations with the Bathysphere

FOUR years ago, Dr William Beebe and Mr Otis Barton descended in their 'bathysphere'—a steel ball fitted with quartz windows—to a depth of a quarter of a mile below the surface of the ocean off Bermuda. During the season of 1934 they successfully established a new depth record of 3,028 ft In the *National Geographic Magazine* of December 1934 and the *Bulletin of the New York Zoological Society* of November–December 1934, interesting articles deal with the fitting-out, operation and scientific observations made, during these latest dives Excellent photographs in the text provide a word picture of the undertaking, and a series of coloured plates give vivid impressions of the strange and bizarre forms of life as seen by Dr Beebe through the windows of the ball and described over the telephone line between the bathysphere below and the parent ship at the surface Three deep sea fish, new to science, are described, including the five lined constellation fish, *Bathysidus pentagrammus*, which Dr Beebe speaks of as one of the most gorgeous deep-sea inhabitants he has ever seen Five rows of photophores emitting yellow and purple light produced a beautiful pattern of illumination through the darkness From this and other records, there can be little doubt as to the success and scientific value of this daring method of observation

Optical Research

AT the meetings of the Institut d'Optique, held periodically at the Sorbonne and generally under the chairmanship of Prof. Charles Fabry, director of the Institut, the communications considered relate as a rule to one particular branch of the subject, and the *Revue d'Optique Theorique et Instrumentale* issues a separate copy of the proceedings which may run to as much as 50 pages Last year, the January meeting dealt with the employment of liquid prisms in spectrographs, that of March with interference methods of studying movements of the air, the April meeting with ultra-violet polarimetry and with the densities of photographic images, and the June meeting with the light of the night sky In several cases the subject is introduced by a short sketch of past work on it and its present aims and problems, given by the president, and descriptions of current methods and instruments by specialists in the subject follow These pamphlets seem capable of affording great assistance to those requiring brief résumés of the present positions of the various branches of optical research

Systematics of the Diptera

MR. P H. GRIMSHAW has recently published a useful article entitled "Introduction to the Study of Diptera, with a Key for the Identification of Families" (*Proc Roy. Phys. Soc., Edin.*, **22**, Pt. 4, July 1934) The paper gives a clear account, accompanied by illustrations, of the various structural features of importance in classification A list of the chief general works on the order is provided and a diagnostic key to all the existing families The key is translated and adapted from Lindner's "Fliegen der palaearktischen Region" and should prove especially valuable to those entomologists who are not specialists in the insect order concerned

Review of Seismology

THE National Research Council of the National Academy of Sciences at Washington is issuing a series of bulletins on the physics of the earth, to give scientific workers who are not specialists in the subjects treated an idea of the position and problems of various branches of geophysics Among the bulletins in this series which have already been issued are those on volcanology, the figure of the earth, meteorology, the age of the earth and oceanography Recently, Bulletin No 90 on seismology has appeared It has been prepared by a Committee of which Prof J B Macelwane is chairman Within 219 pages it includes twenty chapters, and gives a very valuable and interesting general view of the subject Chapters by the chairman include the definition and classification of earthquakes, tectonic earthquakes, plutonic earthquakes, rock fall earthquakes, body waves, reflection and refraction of seismic waves, surface waves and paths and velocities of seismic waves within the earth, H O Woods contributes articles on volcanic earthquakes, field investigation and surface geology in relation to the 'apparent' intensity; articles by H F. Reid deal with magnetic effects, earthquake mechanics and with the focus The principle of the seismograph is described by J A Anderson, and P Byerly contributes five articles on analysis of seismograms in earthquakes, records at intermediate and great distances, time distance curves, reduction of trace amplitude, and seismic geography The Bulletin has numerous bibliographies and is priced at 2 dollars.

Books on Anthropology and Archæology

CATALOGUE No 574 (Anthropology and Folklore—Archaeology and Ethnography) issued by Messrs Francis Edwards, Ltd, 83 High Street, Marylebone, London, W 1, including both new and second-hand books, though, naturally, the latter predominate, contains just under a thousand items On looking through the list, two points occur, one being the high average in the quality of the books from the point of view of the anthropologist, and secondly the fact that, with certain exceptions, the prices do not rule high With regard to the first point, the subjects covered by the catalogue, it is almost needless to say, have been a happy hunting ground for the wilder theorist and speculation has been rife in their literature It is evident that here on the whole a wide discretion has been exercised in selection The question of price is no less interesting. It is not intended to convey that this catalogue is an exceptional opportunity for bargain hunters—although it would be possible to form from its pages an excellent nucleus of a reference

library in anthropology at a very moderate price—but rather that the rarities, and even some of the older standard books which command a high price, are becoming increasingly rare. Among the items to be noted are some complete runs of scientific publications, such as the Folklore Society's publications and those of the Royal Anthropological Institute, some lengthy runs of *Archæologia* and a virtually complete set of the *Journal of the African Society*, of which certain numbers are now impossible to obtain, except by fortunate accident A noteworthy item is Edge Partington's ethnographic album of the Pacific, of which, it is thought, not more than half a dozen copies are now in existence in private hands

Announcements

THE following have recently been elected foreign members of the Royal Academy of Sciences, Stockholm Prof Robert Robinson, professor of chemistry in the University of Oxford, Prof F D. Adams, emeritus Logan professor of geology in the McGill University, Montreal, Prof Ejnar Hertzsprung, professor of astrophysics in the University of Leyden, Holland, and Prof A V Hill, Foulerton research professor of the Royal Society, formerly Jodrell professor of physiology in University College, London

AT the annual general meeting of the Royal Astronomical Society held on February 8, the following officers were elected *President:* Mr J H Reynolds, *Vice-Presidents:* Prof S. Chapman, Dr H. Spencer Jones, Dr H Knox-Shaw, Prof F J M Stratton, *Treasurer* Sir Frank W Dyson, *Secretaries*. Mr W M H Greaves and Dr W M Smart, *Foreign Secretary* Prof Alfred Fowler

MR B H WILSDON has been appointed to the post of director of research to the Wool Industries Research Association at Torridon, Headingley, Leeds Since 1929, Mr Wilsdon has been assistant director and superintendent of the Building Research Station of the Department of Scientific and Industrial Research He was educated at Lincoln College, Oxford, and after a period of research there, went to India as a professor of chemistry, afterwards gaining varied experience in applied research in agriculture and organising the Irrigation Research Institute of the Punjab Besides publishing work on chemical and physical subjects, Mr Wilsdon has done pioneer work on the application of statistical methods to industrial problems of specification and standardisation

IN NATURE of February 9 (p 212), it was stated, following the Report for 1933–34 of the Department of Scientific and Industrial Research, that the new process of the Wool Industries Research Association for the production of unshrinkable fabrics is being exploited under mill conditions and that materials should be available to the public early this year. We are informed by the Association that work still remains to be done on the problems which occur in transferring the operation of such a process from the laboratory to a commercial scale, and that "it is certain that underwear or other knitted materials, finished by application of the W.I R A.'s new unshrinkable process, will not be available to the Trade before 1936"

THE Secretary of State for the Colonies has made the following appointments Mr R M Gambles, to be veterinary officer, Cyprus, Mr. J. D. Tallantire, to be superintendent of agriculture, Nigeria; Mr J M S Usher-Wilson, to be superintendent of agriculture, Nigeria, Mr R L Brooks (deputy conservator of forests), to be conservator of forests, Trinidad, Mr P E Carcenac (assistant conservator of forests, Mauritius), to be assistant conservator of forests, Malaya, Mr J de Meza (veterinary bacteriologist), to be chief veterinary officer, Nyasaland, Mr J C Muir (superintendent of agriculture, Gold Coast), to be senior agricultural officer, Zanzibar, Mr F B L Butler (grader and inspector, Agricultural Department, Kenya), to be chief grader and inspector of produce, Agricultural Department, Cyprus

THE twenty-fifth Dutch Congress of Natural Science and Medicine will be held in Leyden on April 23-25 under the presidency of Prof J van der Hoeve with Prof L G. M Baas Becking as president of the biological section and Prof E Gorter as president of the medical section Further information can be obtained from the general secretaries, Dr D. Coelingh, Regenteslaan 2, and D. N R. Pekelharing, Jr, Meentweg 48, Bussum.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—Probationer mapping assistants to H M Land Registry—The Secretary, Civil Service Commission, Burlington Gardens, London, W 1 (Feb. 21) A head of the Engineering Department of the Willesden Technical College—The Secretary, H M Walton (T), 10 Great George Street, Westminster, S W 1 (Feb. 22) A lecturer in electrical engineering at Norwich Technical College—The Principal (Feb 25) A lecturer in electrical engineering at Chesterfield Technical College—The Director of Education, County Education Office, St Mary's Gate, Derby (Feb 25) A computer (Class II, male or female) for the Ordnance Committee, Royal Arsenal, Woolwich, S E 18—The Secretary (Feb 25) A principal of the South-East Essex Technical College—The Director of Education, County Offices, Chelmsford (Feb 28). A lecturer in pathology in the University of Bristol—The Registrar (March 1) A lecturer in bacteriology in the University of Manchester and assistant bacteriologist in the Public Health Laboratory—The Secretary, University, Birmingham 3 (March 1) Junior scientific officers at the National Physical Laboratory to work in the Aerodynamics and Radio Departments—The Director (March 4) Probationary assistant engineers in the Post Office Engineering Department—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1 (March 7) A lecturer in anatomy and deputy-director of the Department at St. Thomas's Hospital Medical School, Lambeth Palace Road, London, S E 1 (March 16) Laboratory assistants (male) at the Experimental Station, Porton, near Salisbury—The Commandant.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 271

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Viscosity of Helium I and Helium II

DETERMINATIONS have recently been made in the Cryogenic Laboratory at Toronto of the viscosity of liquid helium in its two states, helium I and helium II

Helium I denotes the liquid as it first forms at a temperature of 4·2° K When the pressure above the liquid is progressively reduced, the temperature falls and the liquid bubbles freely as it boils under the reduced pressure Suddenly, when a temperature of 2 2° K is reached, the liquid changes its state—a change indicated by complete cessation of boiling, although the temperature continues to fall as pumping is continued.

The viscosity of liquid helium was measured, step by step as the temperature was reduced, by means of observation of the logarithmic decrement and periodic time of the oscillation of a circular metal cylinder submerged in the liquid helium The cylinder was 2 5 cm in diameter, and 8 5 cm in length over all, the top and bottom being bevelled in the form of cones, each 2 1 cm in height. From the top of the cylinder a stiff phosphor-bronze rod 0 07 cm in diameter extended 62·5 cm The rod and cylinder were suspended by a fine phosphor bronze ribbon 14 0 cm long The rod was sufficiently long to ensure that the suspension wire was kept at room temperature

Fuller reports of the experiment will be made elsewhere: the results only are announced here

Helium I at 4·2° K . $\eta = 0\ 00011$ C G S. units
Helium I at 2·3° K . $\eta = 0\ 00027$,, ,,
Helium II at 2·2° K : $\eta = 0\ 000033$,, ,,

To show the definiteness of the viscosity change we may cite the following. During the course of the experiments the cylinder was set swinging in helium II (<2·2° K) and the pressure over the helium liquid was allowed to change to that corresponding to a temperature of 2·7° K. The cylinder continued to oscillate throughout the interval of this change of temperature, but as the state of the liquid changed from II to I, there was a very distinct and abrupt change in the logarithmic decrement, which corresponded to the above changes in the coefficient of viscosity.

This work was carried out by Messrs Wilhelm, Misener and A. R. Clarke

An Application of Infra-Red Photography to Palæobotanical Research

TRANSFER preparations of fossil plants, particularly those of Carboniferous age, provide the palæobotanist with the plant remains separated from the rock matrix and mounted on a transparent base of Canada balsam or cellulose ester While many of these fossil remains are translucent and give the investigator the opportunity of studying some of their microscopic features by transmitted light, many are opaque with ordinary types of illumination.

FIG 1 Photographs of transfer preparation of a fossil plant (1) by ordinary photographic plate, (2) by panchromatic plate, (3) by infra-red plate

It has been found that some of these apparently opaque fossils are translucent with respect to infra-red rays, and photographs taken on plates sensitive to the infra-red part of the spectrum reveal quite a considerable amount of detail otherwise invisible. The accompanying illustration (Fig 1) includes (1) a photograph by transmitted light of a fossil plant of Coal Measure age taken on an ordinary photographic plate, (2) is the same subject taken on a panchromatic plate with a dark red filter, and (3) is the same subject taken on an infra red plate with an infra-red filter The exposure required with the panchromatic plate was considerably longer than that required for the two other photographs The exposure with the infra-red was one minute The magnification is in each case 6 5.

It is clear that since this fossil is a thin layer of coal, this method of examining carbonaceous fossil plants may be very effective in coal petrology in the examination of coal in thin sections.

Scattering of Hard γ-Rays and Annihilation Radiation

To determine the relative importance of the annihilation of positive electrons in the phenomenon of the 'scattering' of hard γ-rays, observations were made on the secondary γ-radiation from thin lead foils irradiated with thorium C″ γ-rays (25 mgm) With a scattering angle of about 140°, 0 8 cm effective lead filter was sufficient to absorb practically all the Compton scattering, and still leave predominant the softer of the two components in the anomalous scattering, namely, the component which has been attributed to the annihilation of positive electrons

A sheet of paraffin wax was placed in front of the source to reduce to a minimum the number of positive electrons falling on the scatterer Measurements were made on the secondary γ radiation from foils of varying thicknesses (t) down to thicknesses of the order of, and appreciably less than, the average range (R) of the positive electrons, expected from theory, from the γ rays used. If the annihilation hypothesis is correct, the 'scattered' radiation under these conditions should, in the region $t \sim R$, decrease much more rapidly with decreasing t than its first power, owing to the escape of the positive electrons from the foil before annihilation This rapid decrease was actually found, the effect of the thinnest foil used ($\sim 0\ 002$ cm) being only about 30 per cent of the value corresponding to a linear variation with t This shows that at least about 70 per cent of the scattered radiation under these conditions is due to annihilation[1]

To test further the annihilation theory of the origin of the *soft* component, it was compared, under practically identical conditions, with the Compton scattering through 79°, this angle of scattering giving Compton radiation of the same wave-length, namely h/mc, as that of the theoretical annihilation radiation Both in frequency and intensity the soft component was found to agree fairly well with the theoretical expectations, and there is no question, according to the present experiments, of the annihilation radiation being only a small fraction of the theoretical value, as maintained by Bothe and Horn[2] The theoretical intensity was estimated in the usual way from the number of positive electrons produced by the primary γ-rays according to Dirac's theory[3]

To investigate the *hard* component in the anomalous scattering, observations were made with different thicknesses of lead filter in the path of the secondary rays, up to 5 cm of lead at 140°, and up to 7 cm at 80° While a slight progressive hardening was found with increasing filter strength, throughout this range, there was no evidence for secondary radiation of primary hardness Actually, with the maximum filter thickness, the secondary radiation was definitely softer than the hard γ-rays from radium C. The latter correspond to a quantum energy of about $1{\cdot}9 \times 10^6$ volts, while the effective primary radiation in the above experiments has a quantum energy of $2{\cdot}65 \times 10^6$ volts

The initial intensity of the hard component from lead is of the order of 15 per cent of that of the half-million volt radiation It is somewhat anisotropic, being more intense at 80° than at 140° The anisotropy is more pronounced for light elements. These results are qualitatively in agreement with the supposition that the hard component is due to X-radiation from Compton electrons, and the annihilation of positive electrons before reaching the end of their range, the degree of anisotropy of such tertiary radiations being dependent on the atomic number through the nuclear scattering of the secondary electrons The importance of the first of these processes has already been emphasised by Lauritsen and Oppenheimer[4], and from more recent and detailed calculations by Wheeler and Plesset[5] it appears that the two processes will account for at least a large part of the hard component

A fuller account of the experiments described in this note, and of a more detailed analysis of the results when completed, will be published in due course The experiments were carried out at the laboratory of the Institute for Theoretical Physics, Copenhagen, and I should like to take this opportunity of thanking Prof N Bohr for his kind interest in the investigation, and also Dr J C Jacobsen and Mr K F Brostrom for their valuable assistance in the experimental work

Colchicine and Tumour Growth

THE finding of considerable numbers of mitotic figures in the hæmopoietic organs of normal healthy animals and in the neoplastic tissues of tumour-bearing animals after colchicine administration has led many students to suspect an inter-relationship between mitosis and the alkaloid But the effect of colchicine in slowing down the rate of growth of neoplastic tissue has not been reported

Following on some earlier observations (unpublished, 1927) which I made in conjunction with the late Prof M R J. Hayes on the beneficial effects of deep X-ray therapy on neoplasms in patients suffering from acute attacks of gout, which were being treated with colchicum, a series of experiments was recently planned with the object of determining to what extent the colchicine might affect new growths

In one of these, a group of twelve tumour-bearing mice (*M* **63**), were injected subcutaneously on alternate days with small doses of colchicine (kindly supplied by the director of the Wellcome Bureau of Scientific Research, where the work was carried out) Treatment lasted for a period of two weeks. Twelve other tumour-bearing mice were used as controls. The tumours at the end of the first week showed much less growth as compared with the controls; while at the end of the second week there was no macroscopically recognisable tumour tissue present in 66 6 per cent of the injected animals, and only minute nodules could be detected in the remaining 33·3 per cent These nodules finally showed complete regression, and no tumour tissue could be recognised eight weeks later The controls in all but one instance showed a marked development of the tumour In another series, the percentage of animals in which there was no recognisable tumour tissue at the end of two weeks was 100 per cent

From the effects observed in these tumour-bearing mice, it was thought advisable to determine what

effects, if any, could be obtained in dogs with spontaneous tumours. Of several dogs treated or undergoing treatment with colchicine, the changes observed in a spontaneous tumour in the peritonsillar region in one of these animals is sufficiently striking to warrant recording

Case history Sealyham, 11 years old. Difficulty in swallowing biscuits observed about August 26, 1934 By September 30 a marked tendency for holding his head on the left side had developed On November 19 it was difficult and painful to open the mouth The difficulty in deglutition had increased, and the animal was unable to bark On examination there was seen an ulcerated tumour on the left side of the bucal mucous membrane just ventral to the anterior pillars of the fauces on the left side, about the size of a walnut The dog was admitted to the Royal Veterinary College on December 19, 1934, and injections of colchicine were begun, following on the clinical diagnosis of epithelioma Injections were continued on alternate days and on January 9, 1935, a small portion of the tumour was excised for histological examination The clinical diagnosis was confirmed The administration of colchicine was continued and the tumour inspected daily There was a progressive diminution in the size of the growth, and on January 29 only a small scar remained at the site of the original growth

These experiments are being continued with various transplantable tumours, and a number of animals with spontaneous tumours are being treated with colchicine

The significance of these and other facts relating to the effects of colchicine in man and other animals, as well as the effects of such agents as X-rays and radium in combination with colchicine on new growths, will be published and discussed in collaboration with Dr G M Findlay, of the Wellcome Bureau of Scientific Research, to whom I am indebted for facilities and assistance in carrying out this research

Identity of Vitamin B_2 and Flavine and the Nomenclature of Vitamins

ELVEHJEM and Koehn have stated[1] that vitamin B_2 and flavines are not identical Now Elvehjem and Koehn work with chicks, while Goldberger and others, who were the first to adopt the notation '*P-P* factor', which was afterwards called vitamin B_2, have used dogs and rats for their experiments The first symptom that they describe for their rats was "a tendency of the lids of one or both eyes to adhere together with, in some instances, an accumulation of dried secretion on the margins of the lid"

It is precisely this pathological condition which we have been able to cure by lactoflavine The lactoflavine that we used was prepared from milk, according to the methods devised by Kuhn Further, Miss Chick and others, who were among the first to use the notation vitamin B_2, found that a preparation of egg-white is rich in vitamin B_2. Mr. Tierie, in our laboratory, found, on exposing that extract from egg-white to sunlight, that the vitamin is lost; this suggests that this vitamin, which Miss Chick called vitamin B_2, is a flavine. Therefore I think that Kuhn is right in calling his lactoflavine vitamin B_2

These investigations demonstrate, I think, that we are adopting the wrong method in our nomenclature of vitamins by denominating them according to the letters of the alphabet When we isolate more of them—and I am sure there are still several as yet unknown vitamins—we have the trouble of giving them the right letters, and there is again the danger that two investigators may claim the same letter for quite different substances, as is the case with vitamin B_3 Also, the old system is not at all logical vitamins B_1 and B_2 are not only quite different substances, but have also very different actions, on the other hand, vitamins D_1 and D_2 probably do not differ very much in structure, and in action differ only quantitatively.

I should like to propose, therefore, to omit all these letters in the denomination of vitamins The vitamins that are isolated in a pure state should be given their proper names, as has already been done for some of them. So long as they remain unisolated, they may receive a provisional name, just as in the case of hormones Hence vitamin A may provisionally be called anti xerophthalmic-vitamin

Further, I propose to call the present vitamin B_1 in the future aneurin (from a[nti poly]neur[itis vitam]in). I think I have some right to propose this, as Dr Donath and I were the first to obtain this vitamin in a crystalline state

Of the other B vitamins, one is called flavin Whether this is the specific anti-pellagra vitamin or not may soon be known, when the pure flavin is tested on human pellagra patients

Vitamin C is already called ascorbic acid by Szent-Gyorgyi, which name has come into general use

One preparation of vitamin D is already called calciferol As soon as the antirachitic factor from cod liver oil, which is certainly a different substance from calciferol, is prepared in a pure state, it will receive a name

The E vitamins may provisionally be called sex-vitamins or anti sterility vitamins

It is a pity that there is no international committee to regulate this nomenclature

Aluminium Chloride as a Catalyst of Hydrogen Interchange

THE Friedel Crafts reaction

$$RCl + C_6H_6 \xrightarrow{AlCl_3} C_6H_5R + HCl$$

suggests the use of $AlCl_3$ as a catalyst for the interchange of hydrogen between benzene and hydrogen chloride We have found this expectation confirmed in the following experiments: 0 5 gm of $AlCl_3$ was brought into contact, for three hours, in a vessel of about 100 c c capacity, with a mixture of ordinary benzene and hydrogen chloride containing 13 4 per cent D, the temperature in two runs being 25° and 50° respectively

Temp	Benzene	Pressure of hydrogen chloride	Per cent D in hydrogen chloride after treatment
25°	0 107 g	178 mm.	1 23
50°	0 095 g	297 mm	1 08

From the analysis of the hydrogen chloride given in column 4, it follows that in both cases more than 90 per cent of the D had passed over from the hydrogen chloride into the benzene. This has been confirmed by analysing the benzene formed. We have found indications that under the above experimental conditions the reaction proceeds to some extent, even when no $AlCl_3$ is present, but in this case it goes at a much slower rate.

Crystal Structure of Cyanuric Triazide

IN connexion with the discussion on dipole moments held by the Faraday Society at Oxford in April 1934, Sir William Bragg described[1] briefly the results of a research, which I had been making on the structure of cyanuric triazide. A Fourier analysis of the measured X-ray intensities of (*hk*0) planes showed the three nitrogen atoms of the azide group to be in a straight line[2]. Details of the research were promised later and were held up for an absolute intensity determination to be made. The calculations are now completed and will, I hope, be published soon.

Mr. E. W. Hughes has now published[3] a structure which resembles mine, but differs from it in certain important features. He shows the azide group as departing from linearity by 15°, while I find that any departure from the straight line could not exceed 3° or 4°. The distances between the centres of the atoms in the cyanuric ring he finds to be all equal, thus indicating an oscillating double bond as in benzene. I find these distances alternately larger and smaller, corresponding with fixed single and double bonds respectively. The inter-atomic distances which I find are not in complete agreement with his. Mr. Hughes's estimates of the intensity of X-ray reflections were made by eye and I cannot think this a sufficiently safe or accurate method for the purpose. My measurements were made by means of a Robinson photometer and put on an absolute scale by the accurate method of the ionisation chamber.

Spectra and Latent Energy in Flame Gases

IN a recent letter on the above subject, Prof. W. T. David[1] points out that after flame has travelled through an inflammable gaseous mixture, the gases remaining emit luminous (visible and ultra-violet) radiation for a considerable period of time if their temperature is kept up. In an investigation carried out at the United States Bureau of Standards, accounts of which have already appeared[2,3,4], evidence of prolonged emission in the infra-red was obtained from observations of flame in the cylinder of an engine delivering power.

Infra-red radiation (to about 11μ) was recorded from explosions in a small single cylinder L-head engine, through fluorite windows let into the engine head. The fuels used were benzole, and benzole blended with a low-grade petrol. Observations were made of a small depth of charge perpendicular to the direction of flame travel, so that radiation was successively recorded from unburned charge ahead of the flame front, from the flame front, and from gases remaining behind the flame front. Curves of radiation against crank angle were initially horizontal, rose sharply (at the instant visible flame appeared under the window in use) to a maximum, and then decreased gradually.

From gases under a window adjacent to the sparking plug, radiation from non-knocking explosions reached a maximum slightly before maximum pressure was recorded in the cylinder, and at the same instant visible flame appeared under another window, slightly more than 10 cm. away in the direction of flame travel. (This distance corresponded to 20°–25° of engine crank rotation.)

From gases in the 'knocking zone', radiation from non-knocking explosions continued to rise for 20° of crank angle after the arrival of visible flame. In knocking explosions visible flame arrived earlier, and a higher maximum radiation was reached, 15° later as against 20°. For both non-knocking and knocking explosions, maximum pressure in the cylinder preceded maximum radiation.

Later in the cycle, both radiation and pressure curves for knocking explosions were below those for non-knocking, indicating greater loss of energy from the charge involved in the knock.

The fact that radiation through a given window continued to rise for approximately 20° of crank angle after the arrival of flame under that window was taken as evidence that formation of H_2O and CO_2 molecules continued for at least this period, and probably longer, after inflammation. Some doubt was consequently expressed concerning the assumption, based on oxygen determinations at successive moments during the cycle, that combustion is completed in a narrow flame front[5].

It may be that, in an engine cylinder, some metastable H_2O and CO_2 molecules are formed, which then part with their latent energy, either communicating it to neighbouring molecules or emitting radiation on the wave-lengths characteristic of H_2O and CO_2. This would make it easier to reconcile the 20° lag between the appearance of flame and the attainment of maximum radiation in the infra red, with the shorter period required for combustion to be completed in a narrow flame front. It is also possible that the phenomenon of fuel-knock may be connected with the proportion of metastable molecules formed during combustion.

Diamagnetism of Light and Heavy Water

THE molecular diamagnetism of light water, 12·97, has been closely approached in the values hitherto published for heavy water: 12·90[1] and 12·76[2]. A coincidence has been observed in this department by J. H. Cruickshank, using a Curie-Chéneveau magnetic balance: the molecular diamagnetism of heavy water was 12·96 ± 0·02. Additional measurements

on light/heavy water mixtures, containing 44, 62 and 87 per cent of heavy water, showed strictly additive susceptibility H_2O, D_2O and HDO therefore appear to have identical molecular diamagnetisms, and to have no influence on one another's magnetism

J H Cruickshank, however, has carried out a more refined measurement, and noticed a peculiar lag in which appears an observable magnetic difference between the two waters The change in susceptibility of freshly melted water, the temperature of which had been allowed to rise to that of the balance, 18° C, was followed over a period of 30 minutes after melting by continuously reading the deflexions The readings gradually increased to a maximum at 20 minutes after melting, and then fell slightly to a constant value

According to recent views[3,4], the state of co-ordination of water is such that the molecules are, for geometric reasons, held farther apart than they would be in a state of closest packing Therefore, although the local effect of co ordination is to lower the diamagnetism at the bonds, the volume effect prevents depression at other points and keeps the diamagnetism up In ice, co ordination is a maximum, in freshly melted water, there is a lag in deco ordination shown by a continuous change in the susceptibility This change is an increase to begin with, because the deco ordination local effect (with its rise of diamagnetism) is predominant Later, the corresponding volume effect (with its fall of diamagnetism) becomes more effective, as seen in the development of a maximum value

In heavy water, both the increase in susceptibility to the maximum value and the subsequent fall to constant value are less than in light water, but take place in the same time Deco-ordination in heavy water tends to take place less readily than in light, but the higher degree of co ordination in the equilibrium state, and the accelerating effect on deco-ordination of the higher initial temperature, 3 8° C, counteract this tendency, with the result that equilibrium is reached in the same time as for light water The rise to and the fall from the maximum susceptibility are less because the total loss of co-ordination required to reach equilibrium is less and thus there is less scope for display of lag

It has been assumed that the temperature of the water rose to 18° C before the observations were begun, but the rise in susceptibility due to a still rising temperature requires to be added to the rise in susceptibility due to the local effect of deco-ordination This makes the rise to the maximum greater than the fall to the equilibrium

During an ordinary determination of susceptibility, the lag described here escapes observation because it is finished long before the constant can be determined

The same experiment was tried with benzene m p. 5 4° and aniline m p −8°, but in neither case was a maximum observed, although it could be seen repeatedly with the waters

Spectrum of Doubly Ionised Iodine

WORK on the identification of the lines belonging to this spectrum was begun more than four years ago and a preliminary announcement on a clue obtained which was expected to lead to an analysis of the spectrum was made at the time in these columns[1] That clue, however, did not lead to the expected result, and had to be abandoned Finally, it was realised that the only way of solution, though necessarily a very lengthy and tedious one, was to find all possible differences between the wave-numbers ascribed to this spectrum

For this purpose the measurements made by Kerris[2] were used and, confining the frequency differences up to within about 15,500, nearly 35,000 subtractions were effected From these has been sorted out what is believed to be a genuine regularity among 50 lines of the spectrum The agreement among the various differences occurring in this intercombination is of the order of 0 2 This has led to the identification of most of the terms in the 6s and 6p levels and a few in the 5d level The relative values of the terms are –

6p level	0, 68 5, 1731 0, 2790 7, 4851 0, 5071 4, 6587 1, 8193·7, 10965 2, 12988 9.
6s level	28222 3, 29630 3, 29908 9, 30272 0, 30503 0, 32839 7, 35299 4
5d level	24618 6, 27004 7, 40686 6

Details of the work up to date are being sent for publication in the *Indian Journal of Physics*

'Viscacelle' as a Material for making Compensating Plates and Wedges for the Polarising Microscope

'VISCACELLE' (cellulose sheet manufactured by Messrs Courtaulds by the viscose process and used extensively as a wrapping material) is birefringent There seems little doubt that this property is due to a net orientation of the long cellulose molecules caused by the unidirectional tension to which the sheet is subjected while being 'spun' Under this tension, the molecules may be expected to arrange themselves so that their length directions are parallel or nearly parallel to the direction of tension This explanation is supported by the fact that the direction of tension (revealed on cut sheets by parallel streaks) is the 'slow' direction of vibration

The accompanying table gives some relevant properties of specimens of different grades of 'Viscacelle' supplied by Messrs Courtaulds The relative retardations were deduced from the polarisation colours by means of Lévy's colour chart of birefringences

Manufacturer's Classification	Thickness (mm)	Polarisation Colour and Relative Retardation ($m\mu$)
300 Ordinary, Grade 1	0 020 – 0 025	(3 layers) purplish red, c 575
300 Ordinary, Grade 2	0 020 – 0 025	(3 layers) orange red, 450–480
400 Ordinary, Grade 1	0 025 – 0 030	(3 layers) bright blue, c 650
600 Ordinary, Grade 1	0 040 – 0 045	(1 layer) pale yellow, 300–340 (2 layers) bright blue, c 650
300 Moistureproof, Grade 1	0 020 – 0 025	(3 layers) bright blue, c 650

The figures show that the thinnest specimens ("300" grades, 0·020–0·025 mm.) have, in single layers, relative retardations approaching, though in the main somewhat greater than that of the quarter-wave mica plate, and a strip of the material bound between two glass slips by means of pieces of gummed label can in fact be used as a satisfactory substitute for this accessory. Three layers of the "300 Ordinary" mounted in the same way can be used in place of the unit retardation selenite plate, whilst a step-wise pile of strips affords an alternative to the mica stepped wedge or quartz wedge. The colours given by such a wedge appear to be quite normal.

It must be emphasised that the figures in the table refer to particular specimens. However, I have examined a number of other specimens taken from proprietary articles without finding wide deviations, and it seems that the birefringence of the material may be taken as roughly constant for a given thickness. It may happen that several specimens of the "300" thickness have to be tried before one is found from which a sensitive red can be built up. It may be mentioned that the higher birefringence of the moistureproof sample (last in table) as compared with others of the same thickness is not connected with its protective coating, for when this was dissolved off with a mixture of acetone and ethyl acetate, no apparent decrease in the birefringence was observed.

I am indebted to Messrs. Courtaulds for supplying graded samples and for information concerning the manufacture and properties of the material.

Dimensions of Electric and Magnetic Units

IF in a recent letter[1] Sir James Henderson uses the word 'dimensions' in its customary sense of relation to the units of length, mass and time, he is arousing false hopes by suggesting the possibility of a 'discovery' of the dimensions of μ_0 and K_0, for these dimensions, and not merely the numerical values of the quantities, are both completely arbitrary, depending upon the units of measurement which may be selected.

It has indeed been proved that $A^2/\mu_0 K_0 = c^2$ where A is the quantity appearing in Ampère's equation and c is the velocity of propagation of electromagnetic waves in a vacuum, but it still remains true that μ_0 and K_0 may each be separately given any values whatever. In some systems of units which have been adopted or discussed, for example, in the Gaussian system, separate values have been assigned to each; in other systems, as in the 'electrostatic' and in the 'electromagnetic' system, a value has been assigned to either K_0 or μ_0 and the other obtained from it by an arbitrary assumption such as $A = 1$, while other recently discussed systems are founded upon the adoption of two independent arbitrary assumptions from which the values of K_0 and μ_0 can be deduced, but for purposes of measurement, as distinguished from historical or more or less sentimental considerations, a system depends only upon the values of K_0 and μ_0 characteristic of it and not at all upon the methods by which these values were finally reached.

It is true that the electronic theory asserts that a magnet is not merely equivalent to but identical with a certain system of electrons in motion, but the argument that this identity necessarily requires the adoption of a system of units in which $\mu_0 = 1$ or in which mL must be dimensionally equal to iL^2 is altogether unsound.

Sir James may readily convince himself of this by the examination of the following simple example. The modern form of the electronic theory obviously suggests the existence of a 'natural' system of electromagnetic measurement in which the unit of electric quantity will be the electron and the unit of magnetic moment will be the Bohr magneton. The 'natural' unit of current will be such that a current i will involve the net passage of i electrons per unit of time and the 'natural' unit of quantity of magnetism will be such that two equal and opposite quantities m of magnetism separated by one unit of length will have a magnetic moment of m magnetons. On this system it is obvious that mL is dimensionally a numeric while the dimensions of iL^2 are L^2/T, and it is easily deducible that the dimensions of K_0 are T^2/ML^3 and of μ_0, T^2/ML^5. The numerical values of these quantities will, of course, depend upon the units of length, mass and time adopted.

It is scarcely necessary to remark that the theoretical charms of such a 'natural' system are totally eclipsed by its practical inconveniences.

Structure of the Caudal Fin of the Cod

WITH reference to Dr. Whitehouse's suggestion[1] that the caudal fin of the cod is of a normal homocercal type, may I state that I have just completed a study of the development of this fin, as a result of which I can affirm that, while it certainly preserves indications of its homocercal origin, it would be misleading to apply the term 'homocercal' to it in its present form.

Whereas in the homocercal fin practically the whole of the web is supported by morphologically ventral skeletal elements belonging to the hypochordal lobe, in the Gadoid fin the upper half of the web is supported by morphologically dorsal elements which arise in a dorsal fin fold, this growing back to fuse with a corresponding ventral fin fold and thus form the symmetrical web. Now Agassiz[2] long ago showed that, because the homocercal fin developed as an exaggeration of heterocercy, the terminal 'axial lobe' of the embryonic caudal fin (in which is included the tip of the notochord) forms a small dorsal lobe to the developing definitive fin. He was, however, unable to find this lobe in the cod, as can be well understood from my own observations, which show that it is suppressed between the developing dorsal and ventral components of the fin; it is here, in other words, medial rather than dorsal in position.

For this and other reasons the term 'pseudocaudal' appears to me to be the most satisfactory designation for the Gadoid fin. A full report and discussion of my results will be published elsewhere.

Evolution and Human Origins

MY attention has been directed to the leading article in the issue of NATURE of January 26 in which criticisms are made on an address by me to the Victoria Institute recently I have no desire to enter into further written controversy on the subject just at present, and you might probably be unable in any case to afford space for it in the pages of NATURE If, however, no notice were taken of the objections urged, it might be considered that silence gave consent or that no answer is possible I beg therefore by your courtesy to say that when, as seems probable, a new edition of the address is published, careful consideration will be given to the arguments in your leading article and such counter-arguments or replies presented as are necessary or possible This will probably be a more convenient way of dealing with them than extending the controversy at the present time in the pages of your valued periodical

More Work for the R.S.P.C A.

MUCH satisfaction must have been felt by lovers of the lower animals in reading the review in NATURE of February 2 (p 164) of the work accomplished by the R S P C A since its foundation in 1824 It encourages one to hope that the Society will delay no longer in pressing for prohibition of the cruel practice of docking the tails of horses

It is not likely that any serious opposition would be offered to such legislation as may be necessary to render docking a penal offence Something might be accomplished if horses mutilated and disfigured in this senseless manner were disqualified as prize-winners in the show ring, but that would not act as universal prohibition One has but to watch horses thus mutilated when turned out to grass in summer to realise what they suffer from swarms of flies

Fortunately, the practice of docking is not nearly so general as it used to be During the Peninsular War, the Duke of Wellington required all cavalry chargers to be so treated in order that they might be distinguished from those in the French army At the present time, however, the horses of British cavalry and those in all racing and most hunting establishments are not docked, but many farm horses and trotting cobs are still subject to the removal of some of their lower vertebræ

HERBERT MAXWELL

Monreith

Points from Foregoing Letters

THE behaviour of liquid helium indicates that it exists in two forms, helium I and helium II Their viscosities have been determined in Prof E F Burton's laboratory at Toronto It appears that when helium I, which is formed at 4 2° K, is further cooled, it becomes more viscous down to 2 3° K, at 2 2° K the liquid suddenly becomes more fluid as it changes into helium II

Thin layers of carbonaceous fossil plants such as are present in coal, while opaque to ordinary light, allow the passage of infra-red radiation Prof John Walton submits photographs of a fossil plant taken in red and infra-red light, the latter showing marked internal structure.

It has been suggested that γ radiation may be changed into positive electrons and vice versa Dr E J Williams finds that very thin lead foils (about 0 002 cm thick), when irradiated with γ rays from thorium C″, yield less than the calculated amount of secondary γ-rays This he interprets as evidence that the positive electrons produced by the original γ-rays escape from the lead-foils before they are 'annihilated' and changed into the softer secondary γ-rays The more penetrating γ-rays scattered by lead-foil are ascribed to γ-radiation from recoil electrons and to the annihilation of positive electrons before reaching the end of their journey

Colchicine, the active substance from the seeds and corm of the meadow saffron, hitherto used in the treatment of gout, has been found by Dr E C Amoroso to be effective in treating a spontaneous tumour in a dog Dr Amoroso also states that colchicine has effected the regression of tumours transplanted on mice

Prof B C P Jansen supports Kuhn's claim that lactoflavine is identical with the originally described vitamin B_2, since both have identical effects on dogs and rats and are rendered inactive by exposure to sunlight Prof Jansen advocates the use of descriptive names instead of letters to indicate the various vitamins

Prof W T David has put forward the view that 'metastable molecules' account for the after-glow of gases following upon an explosive reaction Dr S Steele recalls previous observations showing prolonged emission of infra-red radiation during the explosive reactions which take place in a combustion engine He suggests that in an engine cylinder some metastable H_2O and CO_2 molecules may be formed

The magnetic susceptibility of freshly melted water increases during the first twenty minutes and then falls to a constant level This is explained by Dr F W Gray and Mr J H. Cruickshank as due to the lag in the rearrangement of the water molecules (each molecule of H_2O is surrounded by four others in a more or less tetrahedron fashion, this arrangement is somewhat different in ice and in water) With heavy water a similar but less pronounced change with time is observed

Dr. N H Hartshorne directs attention to the fact that transparent cellulose sheets behave towards light in a manner similar to that of crystals of mica, selenite and quartz, and in appropriate thicknesses may be substituted for them in making compensating plates and wedges for the polarising microscope

Commenting on a letter from Sir James Henderson, Prof Wilberforce shows that the accepted theory of the identity between magnetic phenomena and electronic motion does not establish, as a necessary deduction, the equations $\mu_0 = 1$, $K_0 = 1/c^2$, but on the contrary suggests a different 'natural' system of electromagnetic measurement attractive in theory but inconvenient in practice The theory of dimensions has often been useful in deducing new physical laws

Research Items

The Bones of Comenius Very shortly after the death of the great Czech scholar, John Amos Comenius, in Holland in 1670, his fame, and even his last resting place were forgotten owing to disturbed conditions both in his native land and in Holland In the earlier part of the nineteenth century his memory was revived, but notwithstanding an abortive attempt to fix the site of his grave in 1871, it was only after the close of the War that the Czechoslovakian Government was able to make arrangements with the Dutch authorities for the disinterment of his remains This was made possible by the discovery of the register recording his interment in November 1670, not in the 'great church' of Naarden, as had previously been thought, but in the 'Walloon' church This edifice, after a varied history, had long been occupied as a military barracks The records showed that the body of Comenius had been deposited in a 'common' grave, in which two further interments had followed after considerable intervals Largely owing to the interest of Mr R J Vonka, of the Czechoslovakian Legation, and Dr R A B Oosterhuis, of Amsterdam, this grave was identified and one of the three skeletons provisionally identified by its position and general condition as that of the great scholar The remains have been examined and measured in detail by Prof A J P van den Broek and Prof J Matiegka, who after a close comparison with portraits of Comenius and such information as is available, pronounce the identification to be in all probability well founded The skull is hyperbrachycephalic (cephalic index of 89 71), hypsicephalic (vertical index 77 64), eurymetopic and mesoprosopic The orbits are large and the nose thin The form and dimensions of the skull, in fact, are such as are frequently encountered in Czechoslovakia Among the more noteworthy features are the breadth of forehead and the fact that, notwithstanding the age of the subject at the time of death, the sutures of the skull had not closed The discovery of the remains and their character and method of identification are described in *Anthropologica* (Académie Tchèque des Sciences et des Arts, Prague, IIme Classe, 1933, just received)

Prehistoric Rock Paintings in Abyssinia The Abbé Breuil describes in *L'Anthropologie* (**44**, No 5-6) a number of rock-paintings in the Harrar (Abyssinia) which he examined in 1933, when Dr Paul Wernert was engaged in the excavation of the palæolithic cave of Porc Epic at Diré Daoua One series of paintings was in the cave and a second was on a rock discovered by P Azaïs at Sourre, sixty kilometres from Diré Daoua The cave of Porc-Epic is situated at the top of a cliff about 200 metres above the right bank of the River Diré-Daoua Its deposits, separated by two thin layers of stalagmite, belong to mesolithic and upper palæolithic cultures analogous to those of Kenya and South Africa In the upper and middle deposits, moustero solutro aurignacian implements are associated with geometrical microliths and a coarse pottery On the right wall are a number of drawings, all more or less schematic, which are partly covered by deposits and, consequently, are older than the more recent stalagmite. The figures are highly conventionalised and, therefore, difficult of identification Approximately, however, a list can be established which includes twenty human figures comparable to the most schematic of southern Spain, one elephant, one lion, two carnivores with pointed muzzle and ears, thirteen antelopes, three Bovidæ, etc Nearly all are in bright red, but there are the remains of earlier figures in yellow ochre and a reddy-brown The only remarkable figure is that of a stag, which is compared with a similar figure from Zara Brouk (Addiet). The paintings on the rock at Sourré are of varied dating, distinguishable by the superpositions They fall into eight classes which belong to two main periods, the five earlier stages being naturalistic, while of the later three, two are schematic phases united by a period of transition There is a hunting scene, but all the remaining figures are of a pastoral character They recall pre- and proto dynastic Egypt The identification of certain of the Bovidæ raises an interesting point bearing on the domestication of these animals

Mitogenetic Radiation The announcement, twelve years ago, by Gurwitsch, of the emission of radiations from rapidly growing tissues, occasioned no little interest and even surprise in biological circles, coming as it did from a histologist with so high a reputation Many have been the attempts to repeat his observations, but the results of succeeding investigators have yielded positive and negative results as consistently as the tossing of a coin Dr J B Bateman has rendered valuable service to biological workers in carrying out a critical survey of the literature of the last dozen years dealing with this subject ("Mitogenetic Radiation", *Biol Rev*, **10**, 1, 42, 1935) The weight of the evidence tends slightly against the existence of such a phenomenon, and there is no ground at all to support the view that mitogenetic radiations, if they exist at all, have anything to do with ultra-violet radiation

Statistics of Variations Dr Hans Günther has recently published a little book which serves as a short but useful introduction to the statistics of variation ("Die Variabilität der Organismen und ihre Normgrenzen" Pp 132 Leipzig Thieme, 1935) It is divided into fourteen sections, some of which may be mentioned as indicating its scope and character the causes and categories of variation, statistical and biometrical methods, the conception of the norm and of the abnormal, the limits of variation and of the norm, various types of biological statistical analysis, and special methods for the comparison of variations, as between, for example, races, populations, the sexes, the right and left halves of the body and different stages of development. Various general questions regarding the nature and limits of variations are discussed

Lamellibranchs and a Cruciform Muscle. Mr Alastair Graham, following up his recent investigations of the cruciform muscle of certain Lamellibranchs (NATURE, Sept. 29, 1934, p 500), has compared in detail the anatomy of five bivalves belonging to the Tellinacea, *Gari tellinella*, *Tellina crassa*, *Macoma balthica*, *Scrobicularia plana* and *Donax vittatus* together with *Cultellus pollucidus* as typical of the Solenidæ, and *Solecurtus scopula* and *S chamosolen* as representing the *Solecurtidæ* (*Proc Roy Soc Edin*, **54** (2), No.

15, 1934) The result of this work, as was foreshadowed in the previous paper, shows that the Solecurtidæ should be classified with the Tellinacea rather than with the Solenidæ. The Solecurtidæ, in common with the Tellinacea, possess a cruciform muscle and in many other respects resemble that group, whereas in the Solenidæ the cruciform muscle is absent. The Solecurtidæ have, however, several features which are characteristic of the Solenidæ and there appears to be an undoubted relationship. As the author suggests, "the Solecurtidæ are to be regarded as a group of Lamellibranchs linking the Tellinacea with the Solenacea, but themselves retaining many more primitive features than do the Solenacea, and therefore falling themselves into the former group." The Solenidæ probably separated from the ancestral forms of the Solecurtidæ and the other Tellinacea before the evolution of a cruciform muscle had taken place, and since their separation have evolved along a well defined line of their own. It is an interesting fact and one not easily explained that in the two estuarine species of the Tellinacea, *Macoma balthica* and *Scrobicularia plana*, the length of the intestine has become greatly elongated by coiling.

New Fresh-Water Mollusca. Mr. Alan Mozley has described several new fresh-water molluscs from northern Asia (*Smithsonian Miscellaneous Collections*, **92**, No. 2, 1934). These were collected during a journey made in the years 1932 and 1933 through certain parts of Siberia and northern Kazakstan, the object of the expedition being to investigate the molluscan fauna of the region. The new species are all very like known British forms, a *Valvata*, a *Lymnaea*, a *Planorbis* and a *Physa*, and there are three new sub-species of *Lymnaea* (*Galba*) *palustris* described. The descriptions are of the shells alone, in some cases at least, only dead shells being obtained. *Valvata antiquilina*, n.sp., from Lake Khomotenoze, apparently lived at some former time when the water level stood considerably higher than at present. *Limnaea palustris sandalensis*, n.subsp., comes from a small somewhat saline lake on the Steppe Sari Dala, south west of Pavlodar, northern Kazakstan. Although distinguishable, these four sub-species resemble one another closely.

Tortrix Moth Pests of Fruit Trees. Messrs. G. L. Hey, of the Murphy Chemical Company, and F. J. D. Thomas, of the East Malling Research Station, have recently published an account of their investigations into the biology of *Cacœcia* (*Tortrix*) *podana*, Scop. (*J. Pomol. and Hort. Sci.*, **12**, No. 4, pp. 293–310, December, 1934). The paper is the first of a series which is intended to include descriptions of a considerable number of Tortricidæ which infest fruit trees in Britain. *C. podana* was first described in 1854, and is now distributed throughout Europe, though it has not yet reached the United States. Characters of the larva in all its seven instars are described in the paper under review, and its depredations in each stage are considered. The pupa and mature insect receive shorter treatment. An extensive list of host plants, and a graphic description of damage done, give an idea of the economic significance of the pest. Methods of control depend upon the host plant. Larvæ can be removed from rhododendrons by spraying with lead arsenate, while this wash has little effect on the pest as it occurs on fruit trees, where the method of feeding is different. Traps placed around a bright light at night exterminate considerable numbers of mature moths, and several parasites of the larva are known.

A Wilt of Snapdragons. A serious disease of snapdragons recently occurred near Pretoria, South Africa. It was very swift in its action, for affected plants were often apparently healthy one day, and permanently wilted the next. The young roots and the base of the stem rotted and were frequently discoloured. The cause of this troublesome malady was investigated by Dr. Margaretha G. Mes ("A Wilt of Snapdragon, *Antirrhinum majus*, in South Africa", *S.A. J. Sci.*, **31**, pp. 281–287, Nov. 1934). Two fungi were isolated from diseased tissues, one belonging to the genus *Phytophthora*, and the other to *Fusarium*, but infection experiments demonstrated that the former was the real pathogen. *Fusarium* was, however, responsible for discoloration of wilted plants. The disease-producing organism was identified as *Phytophthora pini*, var. *antirrhini*, but appears to have been classified also as a form of *P. cactorum*. Zoospores have been demonstrated, and the antheridia and oogonia are typical of the genus.

Vernalisation. Since the publication of Bulletin No. 9 on vernalisation by the Herbage Bureau, Aberystwyth, research on the subject has been proceeding rapidly in the U.S.S.R. The many conflicting statements that have appeared in the scientific and popular literature, however, have made it desirable that an authoritative account of the subject should be given, and the Bureau, with the collaboration of Prof. N. A. Maximov, of the Institute of Grain Husbandry, Saratov, U.S.S.R., has issued a further publication, "The Theoretical Significance of Vernalization" as Bulletin No. 16 in the Herbage Publication Series (Aberystwyth: Imp. Bur. Plant Genetics, 2*s.* 6*d.*). Since the discovery that by subjecting partially soaked seed to low temperatures, winter varieties of cereals could acquire the properties of spring varieties, that is, yield the same summer, the investigations have been extended to other types of plants. In the case of soy bean and cotton, vernalisation is effected by exposure of soaked seed to sufficiently high temperatures, after which fruit is formed successfully, even if subsequent temperatures would normally be too low. On the theoretical side, Lysenko's views are discussed in full, the most important of which seems to be that growth and development are essentially different phenomena. The plant, although in an apparently dormant condition, may be undergoing transitional developmental processes which can be profoundly affected by external conditions. Changes in the nature of the plant's composition are also brought about by vernalisation, both the colloidal properties of the protoplasm and the staining reaction of the embryonic tissue being altered after treatment. The first idea, that vernalisation actually accelerated plant development, is now regarded as needing modification. The truer interpretation seems to be that part of the growth period, which normally takes place in the field, can be transferred back to the early germination stages. The question as to whether or not vernalisation is an irreversible process is still a debatable point.

Recent Changes of Level in Japan. In the latest number of its *Bulletin* (**12**, 851–860, 1934), the Earthquake Research Institute has issued a valuable series of plates that illustrate recent changes of level

in Japan During the last two years, a new line of precise levels has been carried out along the route bordering the east coast from near Tokyo northwards to Kamaisi and thence across the Main Island to Akita Throughout the whole course of more than 350 miles, the crust since the last surveys (usually made between 1894 and 1900) has, with a few small exceptions, subsided The principal movements are described by Messrs T Terada and N Miyabe (*Tokyo Imp Acad Proc*, **10**, 557–560, 1934). They consist of V-shaped depressions, one of which, about 100 miles north north east of Tokyo, has reached a depth of 32 in in about thirty six years It lies in a line with the valley of the River Natui, a zone of frequent earthquakes Another, of about 6 in in thirty-four years, occurs on the cross country route about 36 miles south east of Akita. Some miles nearer the latter town, the curve of depression shows a marked break where it crosses the fault associated with the severe earthquake of March 15, 1914

The Oxygen Afterglow E M Stoddart (*Proc Roy Soc*, A, Dec. 1, 1934) has investigated the afterglow obtained in oxygen, both in electrodeless high-frequency discharges and in discharges between aluminium electrodes Pure oxygen showed no afterglow with electrodeless excitation, whether or not the surfaces of the tube were 'poisoned' with water vapour This poisoning had been found by former workers to be necessary for the afterglow No afterglow was produced by the addition of various other gases including nitrogen With the electrode discharge, no afterglow was found with pure oxygen, but the addition of a little nitrogen produced a powerful afterglow By connecting the tube with a trap cooled in a carbon dioxide freezing mixture, nitric oxide was shown to play a part in the afterglow The afterglow gradually disappeared and nitrogen peroxide could be recovered from the cooled trap. No nitrogen peroxide was found in the electrodeless discharges A spectral examination of the afterglow showed weak diffuse bands which are not oxygen bands The author concludes that nitric oxide is formed by a process involving the metal electrodes in the tube, and that the emitter is the same as is present in the chemiluminescence of nitric oxide and ozone

The Limits of the Continuous β-Ray Spectrum H O W Richardson has recently discussed the low energy β rays of radium E and W. J Henderson has investigated the high energy limit of the β rays from thorium C and C″ (*Proc Roy Soc*, A, Dec 1). The deposit of radium E was made on a thin aluminium foil and was placed in a Wilson expansion chamber The energies of the electrons were deduced from their range, and in evaluating the distribution, corrections were made to allow for the loss of the ends of tracks by passing out of the illuminated field and in other ways. A number of the tracks observed are of secondary origin, but there is some evidence of a low energy group of β-rays from radium E The paper by W J Henderson describes an analysis of fast γ rays from thorium C and C″, using the semicircular magnetic focusing method with a pair of Geiger-Muller counters as a detector The counters are mounted so that a β-ray passes through both counters, which are separated by a thin mica sheet Only coincident discharges of the counters are recorded, and this method reduces by a factor of 25 the effect of the γ-rays from the source, which would otherwise mask the β-rays completely in spite of the lead screening The distribution curves for the sources of thorium B + C + C″ slope steeply down to an end point at $2\cdot25 \times 10^6$ volts, while those for the sources of thorium C″ prepared pure by recoil have an end point at $1\ 795 \times 10^6$ volts Beyond these limits there is a slight background and a line at $H\rho$ 10,280 known to arise from thorium C″ The experiments show that in the two alternative modes of decay of thorium C,

$$\begin{tikzcd}[row sep=small] & \text{Th C}' \arrow[dr, "\alpha"] & \\ \text{Th C} \arrow[ur, "\beta"] \arrow[dr, "\alpha"'] & & \text{Th D}, \\ & \text{Th C}'' \arrow[ur, "\beta"'] & \end{tikzcd}$$

the maximum energies by the two paths balance exactly. This is in accordance with the theoretical suggestions of Ellis and Mott, according to which the maximum energy of the β-rays represents the difference in binding energies between the parent and product nuclei The energy missing when a β-particle of lower energy is emitted has not yet been traced

Magnetic Properties of Bivalent Samarium. Although bivalent samarium compounds have been reported as non-existent, P W Selwood (*J Amer Chem Soc*, **56**, 2392, 1934) has prepared the dibromide by heating the tribromide in hydrogen and has measured its magnetic susceptibility. This is found, at various temperatures between about 100° and 400° abs, to be almost the same as that of tervalent europium This is the result which would be anticipated from the Sommerfeld-Kossel rule, which states that ions with equal numbers of electrons often have very similar properties The arrangement of electrons in tervalent europium is (from the 4*f* shell outwards) $4f^6 5s^2 5p^6$ In bivalent samarium it is probably the 6*s* and one of the 5*d* electrons which are lost, $4f^5 5s^2 5p^6 5d(^2 6s)$ The remaining 5*d* electron, however, migrates to the 4*f* shell, thus producing a configuration identical with that of tervalent europium The result is of added interest because both samarium and europium have anomalous temperature coefficients of magnetic susceptibility. A previously reported discrepancy in the susceptibilities of the compounds Sm_2O_3 and $SmBr_3$, of tervalent samarium, was not found.

Atomic Weight of Protactinium. A specimen of protactinium oxide which showed no impurities by the X-ray method has been prepared and utilised in the determination of the atomic weight of protactinium (A. V Grosse, *J Amer Chem Soc*, **56**, 2501, 1934). Potassium protactinium fluoride, K_2PaF_7, crystallises in beautiful colourless needles, can be dried to constant weight, and can be reconverted into the oxide by treating with sulphuric acid, diluting, precipitating with ammonia and igniting In two determinations, 0·091907 gm and 0 070047 gm of K_2PaF_7 gave, respectively, 0·056274 gm and 0·042913 gm of Pa_2O_5 The atomic weights of protactinium calculated are 230 4 and 230·8, the mean value, 230 6 or 231 ± 0 5, being in good agreement with Aston's mass-spectrograph results on actinium lead (AcD = 207) The compound $PaCl_5$, discovered by Grosse (*J Amer Chem Soc.*, **56**, 2200; 1934), might be more suitable for the precision atomic weight determination planned, but larger quantities of protactinium (which is now available for use in ordinary chemical manipulations) are desirable.

Chlorophyll

THE green colouring matter of plants is a wax-like material of complex chemical structure to which the name chlorophyll was given by Pelletier and Caventou in 1817. It is insoluble in water but soluble in alcohol, ether and other organic solvents. Early investigations of chlorophyll which are important are those of Brewster and Stokes, on the absorption spectrum and fluorescence, and of Edward Schunck on the chemical side. Schunck studied particularly the action of acids on chlorophyll and found that important changes in its physical and chemical properties resulted. The first really fundamental investigations on the chemical structure of chlorophyll were those of Willstätter and his collaborators[1] which showed that there are two green pigments present in leaf green, namely, chlorophyll-*a*, with the formula $C_{55}H_{72}O_5N_4Mg$, a bluish-black solid giving greenish blue solutions, and chlorophyll-*b*, a greenish-black solid giving pure green solutions.

On hydrolysis, chlorophyll yields an alcohol, phytol, $C_{20}H_{40}O$, which has been synthesised, and a complex containing four pyrrole nuclei, the composition of which has been determined by examining the decomposition products phytochlorin-*e* from chlorophyll-*a* and phytorhodin-*g* from chlorophyll-*b*, these two substances being usually called now chlorin *e* and rhodin-*g*. By the action of acids on chlorophyll, a product free from magnesium, called phæophytin, is obtained, separable into two components, *a* and *b*. This in its turn, on treatment with hydrochloric acid, yields two phæophorbides, *a* and *b*. By the further degradation of chlorophyll and its derivatives many products are obtained, known as porphyrins.

Since Willstätter's pioneer work, the investigation of chlorophyll and its derivates has been continued mainly by Hans Fischer[2], who has carried out some important syntheses, and by J. B. Conant[3], and their collaborators. The results obtained by these two groups of investigators sometimes differ in points of detail[4]. The present article has the object merely of recording some recent new work on the subject, the present position of which must be sought in the sources given in the references.

A method which has been used in attempts to determine the relations between different substances is hydrogenation. Dietz and Werner[5] now propose to discard this method as leading to very puzzling results difficult to reconcile with other reactions of the substances. Thus, two porphyrins which appear to be isomeric, rhodoporphyrin and isorhodoporphyrin, differ by 0.8–1.2 molecules of hydrogen absorbed, whilst they are interconvertible in 50 per cent sulphuric acid at room temperature. Transformation also occurs slowly in cold concentrated hydrochloric acid and more rapidly in glacial acetic acid with dry hydrogen bromide. If the difference in hydrogen absorption is regarded as indicating a difference in hydrogen content, the acid transformations must be reductions, which seems very unlikely.

The hydrogenation results show only a small difference between the chlorins and true porphyrins. If these results are accepted, chlorophyll and the chlorins are to be regarded as dihydroisoporphyrins in basic structure and also isomeric with true porphyrins, as Fischer postulates. The American workers, however, while continuing to assume that the fundamental nucleus of chlorophyll and the chlorins is that of a dihydroisoporphyrin, postulate that it is also that of a dihydroporphyrin, these being of an equal state of hydrogenation.

A very interesting new method of attack has now been developed by Conant, Chow and Dietz[6], namely the potentiometric titration in acetic acid solution of the basic groups in chlorophyll derivatives. The chlorophyll nucleus and those of its derivatives contain four pyrrole or modified pyrrole rings. An important problem in connexion with the fine structure of the nucleus is the determination of the relative basicities of the four pyrrole nitrogen atoms, which add together to determine the basic character of the whole molecule. Willstätter had utilised the variation in basicity in the chlorophyll series in the method of acid fractionation, which made possible the separation of chlorophyll derivatives in solution, and had also obtained qualitative evidence of the greater basicity of two of the nitrogen atoms by the isolation of dihydrochlorides.

Conant and his collaborators have now supplied quantitative evidence on this problem by a series of potentiometric titrations in glacial acetic acid using a chloranil electrode and perchloric acid as titrating agent, a method which had previously been studied[7]. This electrode makes use of an oxidation-reduction system similar to that in the quinhydrone electrode. Chloranil and its reduction product provide the system in equilibrium with hydrion

$$C_6Cl_4O_2 + 2H^+ \rightleftharpoons C_6Cl_4(OH)_2 + 2\ominus,$$

and a pH scale can thus be derived from it. When the solvent is glacial acetic acid, this pH scale will not, of course, be related directly to the standard hydrion activity as defined for aqueous solutions, but it may be defined in terms of an acidity function by a method discussed by the authors. For comparative purposes this is a secondary consideration, and the values of pH in acetic acid may be calculated by a formula similar to that used for the quinhydrone electrode in aqueous solutions, a particular value being taken for the standard potential. If the reaction between chlorophyll base (B) and acid proton (H^+) is formulated as $B + H^+ \rightleftharpoons BH^+$, the value of pK^1, the dissociation constant of the chlorophyll base, will then be given by

$$pK^1 = pH + \log (BH^+)/(B)$$

in which all symbols refer to the acetic acid solutions. The ionic strength of the solution (which influences the activity coefficients of the solutes) was kept constant at $\mu = 0.2$ by adding the required amounts of the neutral salt trimethylammonium perchlorate. The values of pK^1_1, pK^1_2 and pK^1_3, for the dissociation of the first, second and third basic groups, corresponding to titration mid points for each range, were read directly from the titration curves at added aliquots of 0.5, 1.5 and 2.5 mols of titrating agent, in accordance with the usual *approximate* theory for calculating pK from the pH titration values.

In this way, the values of pK^1 for a series of simple nitrogen compounds (positively and negatively substituted pyrroles, a dipyrrylmethane, two N-methyl methanes and a methylethylmaleic imide) were first determined. These are all about -2.3 ± 0.3, indicating that the pyrrole group is a very weak base. If pyrrole is regarded as a substituted ammonia, the two α, β-unsaturated linkages appear to control the

diminution in basic character of the ammonia nitrogen All the chlorophyll derivatives examined contain at least one and possibly two of the very weakly basic groups (a) or (b)

(a) pyrrole (b) isopyrrole (c) pyrrolenine (d) hydropyrrole

and they gave pK^1_s values of -1 9 to -2 4

With very few exceptions, all these compounds also contain one rather strongly basic group with a pK^1_s value of +1 8 to +2 3, which, as titrations of two methenes indicated, was probably the oxidised pyrrole or pyrrolenine ring (c), having one α, β-unsaturated linkage and a tertiary nitrogen atom Pyridine has also a pK^1 value of +2 93, which is the lower limit of basic strength in the glacial acetic acid system This system gives satisfactory results for basic strengths of compounds such as urea, which have pK in water of about zero, and compounds so weakly basic (for example, acetanilide and acetamide) that they cannot be measured in water

The porphyrins stand out as a group from all other chlorophyll derivatives in containing *two* relatively strong basic groups, of average pK^1 of +2 5 The chlorins are differentiated from the porphyrins in having only *one* relatively strongly basic group, with pK^1 +2 1, and one group intermediate in basicity between the pyrrole and pyrrolenine groups, possibly an oxidation or reduction product of the latter in which the character of the nitrogen atom is changed The basicity of this group is influenced by substituent groups and is comparable with the basicity of urea and acetoxime This result leads to a correction of a previous formula for chlorin *f*, which is now supposed to contain a hydropyrrole nucleus (*d*) in place of one of the two pyrrolenine rings previously assumed by Conant

The true chlorophyll *a* compounds, the phæophorbides, are found to contain one relatively strongly basic and one very weakly basic group, as in the chlorins The intermediate group, however, is less basic than in the chlorins, but whether this difference is significant of a radically different structure is difficult to say In the *b* series, rhodin *l* is the simplest compound and corresponds with chlorin *f* in the *a* series The two basic groups in rhodin *l* are weaker than in the *a* series, but rhodin *g* is very similar to chlorin *e* Methyl phæophorbide-*b* is markedly different from the *a* compound in the relatively strongly basic group It appears that the extra oxygen atom in the *b* series affects the basicity of all the compounds, which would be unlikely if it were in the side chain of the propionic acid group, as postulated by Fischer

The interpretation of the results of the new potentiometric titration experiments is still incomplete and rather tentative, but it is clear that the method promises to throw light on the structure of compounds containing basic groups, and its extension from the chlorophylls and porphyrins into other fields is obvious

Fuel Research in Great Britain*

THE work of the Fuel Research Board touches many aspects of the technology of fuel, and the annual report for the year ending March 1934 therefore provides a useful review of the problems before the coal and other fuel industries

In the first place, the report emphasises the steady accumulation of information by the survey of the coalfields of Great Britain, the value of which becomes increasingly evident as the demands on the properties of fuel become more exacting

Reference is made to the fall in demand for large lump coal in recent years Formerly, collieries made great efforts to avoid breaking coal because the consumer was prepared to pay, for size, a premium which was disproportionate to the calorific value of the coal itself Actually the consumer paid his premium for a fuel the cleanness of which was visible to the eye. Now more than 77 million tons of coal is washed and its quality can be guaranteed, irrespective of size Industrial fuel is nearly always wanted in small pieces, especially when firing is automatic The modern house has little room for storage, and the householder wishes to avoid the trouble and dirt of breaking coal One can foresee a time when the large lumps will become unsaleable, and already some collieries are seeking the best and most efficient manner of breaking down lump coal without the undue formation of dust Many difficult problems arise when coals are broken, such as the best treatment of wash water containing dust, and the staff of the Fuel Research Board is engaged on their examination

A section of the report deals with the liquid fuels from coal A small fraction of the needs of Great Britain is covered by the by-products of coal carbonisation, that is, benzole and coal tar oils Most of the liquid fuel is imported from distant parts where Nature has provided a bounteous though, from our point of view, ill placed supply of oil The geographical distribution of petroleum provides food for speculation as to what the distribution of man might have been had he known of the existence of the oil earlier, or had understood how to obtain, control and distribute the natural gas which accompanies oil in such abundance Industries might have been very differently situated, and it is improbable that men would have toiled against the hazards of coal getting if such an ideal fuel as methane were available without effort Even as it is, Governments all over the world are exerting themselves to turn solid into liquid fuels by processes which are technically speaking heroic but, judged by ordinary standards, uneconomic. The studies of the Fuel

* Department of Scientific and Industrial Research Report of the Fuel Research Board for the Year ended 31st March 1934, with Report of the Director of Fuel Research Pp vii+178 (London H M Stationery Office, 1934) 3s net

Research Board on this problem are interesting because so much of the experience in this field is in private hands

It is shown that a large proportion of coal tars—indeed practically the whole of a low temperature tar—can be hydrogenated to first class motor spirit, and a larger plant for this purpose is being erected As regards the hydrogenation of coal itself, the influence of minor inorganic ingredients is receiving special attention Lubricants are not less important than the fuels and it is found that although some are obtainable from coal products, they are not yet suitable for common use

Considerable attention is being given to the use of pulverised fuel at sea The 'grid' burner for pulverised fuel devised at the Fuel Research Station is now in commercial use Favourable reports are received of the use of pulverised fuel with this burner, and it is claimed to be, in general operation, equal to oil firing in similar furnaces, but more economical both thermally and in cost

A new feature is the appointment of a 'scientific panel' of academic chemists, who are to engage upon *more academic investigation bearing on fuel processes* The Board is also giving financial support, but unfortunately on a scale reduced in 1931, to other investigations in university laboratories H J H

University and Educational Intelligence

CAMBRIDGE —R I N Greaves, of Clare College, has been appointed University demonstrator in pathology Dr J D Boyd, of the Queen's University, Belfast, and R S Handley, of Gonville and Caius College, have been appointed University demonstrators in anatomy.

THE University Catholic Societies in Great Britain, twenty-three in number, are federated in an organisation which is linked with other national student federations through "Pax Romana", an international secretariat to which papal recognition was, for the first time, formally accorded last April The British federation has marked its sense of the importance of this event by publishing in its Year Book for 1934–35 somewhat detailed expositions of its aims and policy and those of Pax Romana, and a report on a pilgrimage to Rome of a party of 130 of its members Its general aim is to assist in the "Catholic education of persons of academic standing", the process being developed *pari passu* with secular studies and comprising, in addition to religious exercises, Catholic philosophy, Catholic social principles, Catholic missionary efforts and Catholic "action in the world at large". Further light on its outlook is to be found in the report, published in the Year Book, of the proceedings of its annual meeting held at Edinburgh on June 29–July 2, 1934. Here the general theme of the discussions was "The Catholic Approach to Knowledge", the chief contributions being papers read by Prof G Temple of King's College, London, on "Man and Knowledge" in which the supreme importance of metaphysics was urged, by Prof. E. T Whittaker on "Man and the Universe" and by Mr. J. A. Lauwerys, of the University of London Institute of Education, on "Man and Life", in which he stresses, as in his book on "Education and Biology", a vitalistic point of view and the importance of teleology.

Science News a Century Ago

Social Economics

On February 16, 1835, a paper by Lieut -Col Sykes was read to the Statistical Society entitled "On the Increase of Wealth and Expenditure in the Various Classes of Society, as indicated by the Returns made to the Tax Office, by Exports, Imports, and Savings Banks" The classes included in this review were the gentry, the trading and manufacturing bodies and the depositors in savings banks, and the author gave some interesting particulars regarding the increase of capital employed in various articles of trade and luxury The increase in population of England, from 1821 to 1831, he said, had been 11·3 per cent (from 11,760,555 to 13,091,005) and for the entire population of Great Britain and Ireland the increase had been somewhat more, from 21,726,924 to 24,306,719 In the same period, the poor rates had risen from £6,674,083 to £8,316,617 The total number of depositors in the savings banks was 475,155 and the amount deposited £15,715,111 In concluding his paper, Col Sykes said it had been his object to offer a practical illustration of the facilities the Statistical Society afforded to everyone to collate facts with the view of showing the actual state and past changes in the condition of society

Civil List Pensions for Men of Science

The recognition by the Government a century ago of eminent men of science led in the first place to the conferment of several knighthoods It was next resolved to grant Civil List pensions The first of these was awarded to Airy, then thirty-four years of age On February 17, 1835, Sir Robert Peel wrote to Airy and in the course of his letter he said "I consider you to have the first claim on the Royal Favour which Eminence in those high Pursuits to which your life is devoted, can give, and I fear that the Emoluments attached to your appointment in the University of Cambridge are hardly sufficient to relieve you from anxiety as to the Future on account of those in whose welfare you are deeply interested "

"The state of the Civil List would enable me to advise the King to grant a pension of three hundred pounds per annum, and if the offer be acceptable to you the Pension shall be granted either to Mrs Airy or yourself as you may prefer "

"I beg you distinctly to understand that your acquiescence in this Proposal, will impose upon you no obligation personal or political in the slightest degree "

Airy replied from the Observatory, Cambridge, on the following day, thanking Sir Robert Peel, and asking that the pension might be settled on Mrs Airy Peel replied on February 19, saying "I will give immediate directions for the preparation of the warrant settling the Pension on Mrs Airy I assure you I never gave an official order which was accompanied with more satisfaction to myself than this "

Wheatstone on Musical Sounds

At King's College, London, on February 17, 1835, Wheatstone delivered an introductory lecture on musical sounds A report of the lecture appeared in the *Athenaeum* of February 21, 1835 After showing how the oscillations of bells and string and wind instruments could be made visible, Wheatstone went on

to the consideration of that modification of sound which constitutes its pitch, and showed that it depends on the frequency of vibration, he also explained the several modes by which this frequency could be estimated He made experiments with Robison's stop-cock and Cagniard de la Tour's syren, and referred to the standard of pitch proposed by Chladni He next dealt with the various experiments made with the view of determining the limits of audibility, with respect to the human ear, dealing particularly with those of Wollaston and Savart, and explained the origin and formation of musical scales. He concluded his lecture with an exhibition of Trevelyan's experiments on the vibration of heated plates, and a mode of producing sounds by an electromagnetic apparatus

One of Faraday's Unsuccessful Researches

At intervals throughout the year 1835, Faraday worked on the preparation of fluorine He had completed the long series of experiments by which he had laid the foundations of electro-chemistry, and had not yet begun his researches on electrostatics In the course of his determinations of electrochemical equivalents, he had found that fused salts as well as aqueous solutions could be electrolysed, in certain cases with the separation of the elements in a free state, and he proposed now to apply the method of electrolysis to fluorides in the hope of devising a method of producing fluorine Thus on February 19, 1835, the "Diary" records the construction of an electrolytic retort, of platinum, with electrodes of the same metal, in which experiments were begun on the electrolysis of fused lead fluoride This research was unsuccessful as regards the production of fluorine It came between two of his great periods of discovery, and was given up at the end of 1835, so that he might begin the electrostatic experiments with the great cube in the Royal Institution lecture theatre It is of interest as an investigation which is described at some length in the "Diary", but of which no record appears in his published work

The South Magnetic Pole

At a meeting of the Royal Society on February 19, 1835, E Rudge read a paper "On the Probable Position of the South Magnetic Pole" The recent discovery of the site of the North Magnetic Pole, which had resulted from the experiments of Capt James Ross, had suggested to the author the inquiry whether any similar indications of an approach to the South Magnetic Pole could be gathered from any observations then on record With this view he gave a table of the observations made by Tasman in 1642 and 1643, during his voyage of discovery in the Southern Ocean, extracted from his journal. From this it appeared that Tasman on one occasion noticed the continual agitation of the horizontal needle, in south latitude 42° 25′ and longitude from Paris 160° On the presumption that the South Magnetic Pole, said the author, was at that time near this spot, and that it had since been retrograding towards the east, he conjectured that it would now be found in or about the 43rd parallel of south latitude, and to the south-east of the Island of Madagascar, a situation extremely convenient for ascertaining its exact position, which he considered an object of great theoretical as well as practical importance

Societies and Academies

London

Royal Society, February 7. E N DA C ANDRADE and P. J. HUTCHINGS Mechanical behaviour of single crystals of mercury. In the mercury crystal the rhombohedral faces are glide planes, and the short diagonal is the glide direction The crystal twins under strain on a plane through the long diagonals of two opposite faces acting as glide planes In simple glide, twinning takes place when the twinning plane makes an angle of 45° with the axis of the wire The rhombohedral face and the hexagonal basal plane are equally close-packed, but the former contains a much more closely packed line than does the latter Double and triple glide can take place Hardening on one set of glide planes hardens the whole crystal The critical shear stress at $-43°$ C is 9·3 gm wt per sq mm E N DA C ANDRADE and J C MARTINDALE Structure and physical properties of thin films of metal on solid surfaces The films were prepared by cathodic sputtering under carefully controlled conditions, with a water-cooled anode The films obtained were uniform, and appear to be amorphous with all types of microscopic examination When they are maintained at a temperature of about 230° for silver, and somewhat higher for gold, the first stage of crystallisation takes place, which consists in the formation of birefringement aggregates, of the order of 1 μ across, showing the spherulitic figure in polarised light Prolonged heating at a somewhat higher temperature leads to rapid growth of the particles, which eventually become well-formed cubic crystals, all arranged with the (111) faces parallel to the supporting surface The first aggregates are formed by the movement of the upper layers of the films, which are about 50 atoms thick, the further growth of the crystals being accompanied by the formation of areas from which the metal has retreated, leaving a thinner film Crystallisation in such thinner films does not take place until a much higher temperature is reached than that required for the thicker films M BORN On the theory of optical activity This paper contains a detailed development of the theory of rotatory power given by the author in 1915 The molecule is considered as consisting of a set of isotropic oscillators coupled by Coulomb forces The interaction is calculated by the perturbation method The resultant formula is rather complicated but can be simplified very much for special cases A molecule consisting of two equal pairs of oscillators perpendicular to one another and to their central line is worked out in detail; it gives the angle of rotation of the expected order of magnitude

Dublin

Royal Dublin Society, December 12 KENNETH C BAILEY: Thermal decomposition of hydrogen peroxide in presence of glass wool and copper sulphate. Hydrogen peroxide decomposes very slowly in the absence of suitable solid surfaces, even in markedly alkaline solution In presence of glass wool, the decomposition is probably complex, and approximately correct results are obtained by using the equation $v = 15[H_2O_2]\,[OH'] + 7 \times 10^{-6}\,[H_2O_2]$, the *amount* of glass wool present having very little influence on the velocity, although the stopping of the reaction in absence of solid surfaces suggests that both first and second order reactions are probably

heterogeneous. In presence of glass wool on the surface of which copper has been adsorbed, the reaction is of zero order, and probably takes place in two stages, a peroxide of copper acting as intermediate compound It seems certain that this reaction follows an entirely different course from that on the surface of glass wool alone, copper ions in solution having little or no effect J LYONS The influence of physical and mechanical treatment on the firmness of butter. When the cream is cooled to a low temperature immediately after pasteurisation, it gives butter which is considerably firmer than cream which is not so cooled Pasteurising cream at unnecessarily high temperatures reduces the firmness The fat content of the cream used for churning and the moisture content of the butter and size of the fat globules in the cream appear to have little influence on the firmness The firmness of butter does not appear to be improved by holding it at a low temperature over a long period.

CONTENTS

History Based on Science

A POWERFUL, learned and convincing book which has just appeared will, it is to be hoped, turn the minds of many people, besides readers of NATURE, to the consideration of the subject raised in the title of this article The book is the second volume of Prof Preserved Smith's "History of Modern Culture",* of which the first volume was noticed in these columns on April 4, 1931 (127, 515) We shall have something further to say about it later on The subject is the large one, still unrecognised by most thinkers in its true greatness, of the part which science has played, and is playing with increasing vigour as we write, in changing and building up the fabric of society

It is, of course, a commonplace that the discoveries and applications of science are the leading feature of our own age Some people deplore the effect of this development on ways of thought and life, others, like M René Sand, more justly, point out the enormous advantages to health and happiness which have already accrued to mankind from this source, and the illimitable supply which is at our command for the future, if we have the wisdom to use it No one disputes the fact But the strange paradox faces us, that, though this is admitted with regard to the present, the historians, those whose business it is to show how the present has arisen from the past, scarcely pay any attention to science at all Yet, surely, here again, we may start from two universally accepted truths; one, that the present is the child of the past and formed by it, two, that man is primarily the thinking animal, so that the history of his thought must be the most important part of his whole history In spite of this, the vast bulk of the history still taught and written deals exclusively with politics and war We are shown how men use and abuse their means of associating with one another We are not shown the nature or the growth of the one thing in which their association is most perfect, and by means of which they have gained their power of controlling the external world

Some people treat this as a purely academic question, to be settled by those who have the matter in hand Authors, they say, must study and write about the things that interest them and their readers. If people want the interest of chemistry, they will get it, and, surely, there are plenty of histories of chemistry? One cannot,

* A History of Modern Culture By Prof Preserved Smith Vol 2 The Enlightenment, 1687–1776 Pp. vii+703. (London George Routledge and Sons, Ltd., 1934) 12s 6d net.

however, just leave the question unanswered, for there is a thing called 'history' quite apart from the special histories of chemistry, art, religion, etc, and it is this general thing, called commonly 'history', to which we are now referring It is that which forms the staple of what is taught in schools as 'history', and of which people think, when asked, if they care about history or know much about it. This common or general thing is made up almost entirely of politics and war, and it is this which statesmen and reformers now have in mind when they set up committees "to examine the historical textbooks and eliminate obnoxious matter" (as now in London), or commission writers to produce new history books, inspired by a certain desired spirit (as now in Germany) Evidently, the men who take this executive action think that there is something to be gained by doing it, and, though they probably exaggerate the possible effects of their action, we must agree with them when they find something more in history than the mere gratification of a special interest and treat it as a matter of profound social and intellectual concern Unfortunately, however, those thus criticising and proscribing history books only deal, as a rule, with the fringes or excrescences of the matter They only notice the special points obnoxious to their own point of view, and the root of the whole mischief escapes them

The best proof of the truth which we are trying to establish—and incidentally the best evidence of the mischief of missing it—is to be found in works where the authors are clearly free from such propagandist intent as we have just instanced, and seem obviously trying to present the facts as they were It happens that a book of great learning and bulk has recently begun to appear in England and has been received with a chorus of approval by the Press This is Prof A J. Toynbee's "Study of History", of which the first three volumes appeared in the autumn and several more are promised It is in many points similar to the more famous work of Spengler, and in the matter now under discussion is open to the same criticism The general thesis, enforced by a wealth of interesting detail, is that history should be regarded as the record of the birth, flowering and decay of a large number of independent civilisations which we may indeed group into more or less cognate families, but which have their hour and pass away like the individuals who compose them Prof Toynbee has in fact a special section in which he denounces the 'misconception' of the 'unity of civilisation', while Herr Spengler, as is well known, has discovered and explains the decay and disappearance of the Western civilisation around which this unity is commonly supposed to rest and to be growing

It is, of course, largely a question of terminology whether we speak of many 'civilisations' which pass away, or of one human 'civilisation' which lasts and grows But there is one supremely important point involved in the belief in a real unity of civilisation, whatever the temporary varieties under which civilisation may appear in China, Egypt, Mexico and the rest, and it is just this one supreme point which the authors mentioned, and many more, completely miss The unity of civilisation does not mean the temporary unification of a large part of the earth's surface whether by an Alexander, a Roman Empire, a Genghis Khan, or the colonising armies of modern Europe It means that the root of human civilisation is *one*, and is to be found in the development of the human mind, which is similar all over the world in its effective contacts with external Nature, and of which science—understood in the widest sense—is the most characteristic and most permanent fruit It is because science in this sense is missed by these theorists, and the hosts of others less learned than they, that we have all this talk about passing away of civilisation, the decay of the West, the bankruptcy of man

If we study carefully the various features of the 'civilisations', described by Prof Toynbee and others as having 'passed away', we find that they consist mainly of forms of art, language and literature, which naturally do attain a perfection of form and then decay or are transformed into other shapes Thus Latin literature reached perfection with Virgil and then decayed The renascence with Dante took a new form, though even here it would be too much to say that Virgil was dead But science differs in this respect profoundly It is not an art-form like a Greek vase or an ode of Horace The changes made in its expression—systems of numeration, use of cipher, indexes, equations and so forth—are not comparable to the temporary laws of metre or to styles in architecture They are rather progressive attempts to simplify the apparatus of thought, to make the common human mind more competent in ordering its thoughts and dealing with phenomena Greek geometry or the Hindu cypher is not a fashion It is absorbed permanently by mankind, and, though it may be further simplified

or put into a still more general form, we all need to use it at some stage of our mental development

This comparative illustration is surely an apt one, and may be extended with due qualifications to science as a whole, which is constantly approximating to the precision of mathematics It is a common human possession, and a living and growing one, being in fact the best guarantee both of the unity of mankind and the future of civilisation Clearly, therefore, on all grounds, it should take a foremost place in our apprehension of history and in our presentations of it to others It is a difficult task, the most difficult perhaps in the whole of education , but it is scarcely too much to say that up to the present the attempts that have been made have either merely scratched the surface, or else burrowed so far below it that the work is not apparent to the mind of the average educated man History remains for the mass that story of political and military events (largely the latter) to which we referred above A book like that of Prof Preserved Smith is, therefore, heartily to be welcomed, for he has the root of the matter in him "Beginning," he tells us, "in the seventeenth century, men began to look forward and not back, to the future and not to the past, for the era of perfection The reason for this is simply the triumph of science By the end of the seventeenth century even the dullest could see that in knowledge of nature his contemporaries were superior to the most renowned of the ancient worthies "

Vol 2 of Prof. Smith's work covers the years from 1687 to 1776, and is called 'The Enlightenment', implying that awakening of the European mind to its possibilities which followed the scientific revolution of the seventeenth century True to his estimate of the relative value of the various factors in the intellectual evolution of the time, Prof Preserved Smith devotes his first section to science, the next to philosophy, the next to history, and so on It is a fairly complete and well-documented account of the intellectual output of nearly a hundred years preceding the French Revolution The author's reading is enormous, his style is clear and often pointed, and his quotations always apt and often amusing But, praise and enjoy it as we may, one cannot feel that we yet have the comprehensive and well-knit survey of history, inspired by science, which is the great desideratum This book is rather an interesting encyclopædia of a definite and important part of modern thought, full of profound reflections connecting one section of the picture with another, but not a forward-moving account of the whole as an expression of the growth of the human soul in that period, which the ideal requires There are so many trees in the forest, and we are so much interested in studying and comparing their shapes, that we tend to forget where it lies on the earth's surface and where it leads us The work of clear but sound synthesis in history still remains very largely to be done, especially in England, which is in practical ways the most historical of countries

In theoretical work of this kind we are now, as often before, outdistanced by others and perhaps most of all by the French This synthesis, the most needed for moral and international reasons, must be based on the subordination of other aspects of history to that of the growth of thought, and it will trace this growth from the humblest beginnings with the first ape-man to the conquering intellect which now embraces the universe

Reviews

Mathematics before the Greeks

Vorlesungen uber Geschichte der antiken mathematischen Wissenschaften Von O Neugebauer Band 1. *Vorgreichische Mathematik* (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen, herausgegeben von R Courant, Band 43) Pp xii+212 (Berlin Julius Springer, 1934) 19.60 gold marks

MUCH work has been done during recent years in the decipherment and elucidation of ancient Babylonian mathematical texts, and most of all by Dr Neugebauer, the editor of this volume It is not too much to say that no such treasure trove has come into the possession of historians of mathematics since the year 1906, when Heiberg discovered in a palimpsest at Constantinople the tract by Archimedes called by him the "Method", which was supposed to have been lost

Since the publication of that work, other things have indeed come to light One is the solution by Archimedes of the problem of inscribing a regular heptagon in a circle , another is the Moscow papyrus acquired by the Museum of Fine Arts at Moscow in 1912 and at length published by W W Struve in 1930. But these things have added much less to our knowledge of ancient mathematics than the series of cuneiform texts the content of which is set out in the volume before us Dealing with Egyptian as well as Babylonian mathematics, Dr Neugebauer justly claims that his is the first

attempt to give a comprehensive view of the history of pre-Greek mathematics, and we cannot be too grateful to him for his admirable exposition It is intended to be followed in due time by two more volumes ; vol 2 will deal with Greek mathematics, while vol 3 will treat of exact astronomy and particularly the classical work of Ptolemy on one hand, and, on the other, Babylonian astronomy of a relatively late date, the facts about which are much less accessible and more difficult to appraise

The present volume is divided into five chapters The first is on the technique of Babylonian numerical calculation (36 pages), the second (41 pages) contains a general historical account of the language and writing of the cuneiform texts, the Babylonian mathematical terminology, and finally the Egyptian hieroglyphic and hieratic scripts Chap iii (30 pages) describes the Babylonian and Egyptian numeral systems, the notation for whole numbers and fractions, and lastly the sexagesimal system of arithmetical notation and its development as a 'position-value' system of the most thorough-going kind Chap iv (56 pages) gives a general and complete account of Egyptian mathematics, the geometry of areas and volumes, arithmetic including fractions and their manipulation, and problems equivalent to elementary algebraical equations Chap v (42 pages) describes at length the whole content of Babylonian mathematics as it now appears in the light of all the texts so far investigated The headings include geometry, arithmetic and algebra Algebra includes linear equations with a number of unknowns, quadratics with one or two unknowns, and some cubic equations ; there are also some problems in simple and compound interest

Babylonian geometry is mostly the mensuration of areas and volumes (π is taken as 3, not such a good value as the Egyptian approximation) ; but calculations of the 'sagitta' of a chord of a circle by means of the lengths of the diameter and the chord, and the converse, involve the use of the Pythagorean theorem of the square of the hypotenuse The Babylonian arithmetic and algebra are far more remarkable, for the dates (about 2000 B C) to which the texts belong In arithmetic the sexagesimal scale is consistently used instead of the decimal ; each number (up to 59) corresponding to our 'digit' means some power of 60 ; numbers are expressed as the sum of descending powers of sixty followed by units and then by successive sexagesimal fractions ; 'position-value' is fully secured by the existence of a sign, corresponding to our 0, to indicate the absence of a particular denomination. The Babylonians did not even trouble to specify any denominations ; they left them to be inferred from the context ; thus 30 may anywhere mean $\frac{1}{2}$ as easily as 30 units, and so on. To divide one number a by another number b, they took the reciprocal of b ($1/b$), expressed it as a sum of successive sexagesimal fractions, and multiplied a by $1/b$ For this purpose they had tables of reciprocals, just as they had multiplication tables, the reciprocal of 1 21 (81 in our notation) is given as 44 26 40, which means in this case 0 44 26 40 (there being no units in the expression but only sexagesimal fractions) ; the product of 1 21 and 0 44 26 40 will be found to be 1

The Babylonians solved quadratics without stating any general formula, but they calculated the root in concrete figures precisely in accordance with the formula as given in our textbooks, the unknown quantities are not called x, y, z (or by any equivalent symbol), but they are the 'length', 'breadth', 'depth', etc, respectively in some geometrical figure Problems leading to some cubic equations constitute somewhat of a puzzle Some produce an equation of the form $x^3 + x^2 = a$, and the key to the solution in this case was discovered by Neugebauer in certain tables of numbers of the form $n^3 + n^2$ Other cases are not yet explained, and it may be that the root was known beforehand and the problem framed accordingly There are some approximations to the square roots of non-square numbers, one uses the approximation $a + (b/2a)$ for $\sqrt{(a^2 + b)}$, which is common in Greek mathematics In view of the Babylonians' proficiency in algebra about 2000–1800 B C, it is extraordinary that no *arithmetical* solutions of quadratic equations (as distinct from geometrical solutions) are found in Greek writers before Heron and Diophantus

In the account of Egyptian mathematics (chap iv), there is not much that is new in substance, but the exposition is succinct and comprehensive, and new points of view frequently emerge, especially with regard to the dexterous way in which the Egyptians manipulated their fractions, which (except for $\frac{2}{3}$ and occasionally $\frac{3}{4}$) were confined to submultiples and sums of such There is a useful discussion of problems 14 and 10 of the Moscow Papyrus, the first of which uses the correct formula for the volume of a frustum of a pyramid with square base, while the second purports to give the superficial area of a certain curved surface It is interesting to note that Dr Neugebauer inclines to Peet's interpretation of the language of the latter problem, which makes the surface measured to be a half-cylinder and not a hemisphere as supposed by Struve.

As a matter of printing, the volume is beautifully produced, altogether, it is a fine piece of work, and cannot be too strongly commended.

T. L. H.

Animal Behaviour

he Behaviour of Animals an Introduction to its Study By Dr E S Russell Pp viii+184+6 plates (London Edward Arnold and Co, 1934) 10s 6d net

THIS small book is a model of its kind, providing, as it does, an excellent summary of the existing knowledge of animal behaviour, and being full of suggestions with regard to further profitable experimentation But it is more than a pleasantly written résumé, compiled by a man who obviously knows his subject and is intrigued by the many problems in this field which seem to defy human understanding It is a challenge to zoologists

With very few exceptions, animal behaviour is a study sadly neglected by professional zoologists in Great Britain, so neglected that its territory has been claimed by the physiologist and psychologist In this fact danger lurks, for, as Dr Russell argues, quite commonly the proper place for the study of animal behaviour is not the laboratory, and since the physiologist and psychologist are not necessarily naturalists, as the zoologist must needs be, the manner in which an animal lives and maintains itself in Nature has been almost completely disregarded

Dr Russell is perfectly justified in his view that *shepherds, fishermen, fanciers and sportsmen* have much of importance to tell the biologist, for those of us who know these men and have captured their interest are greatly indebted to them They have vast stores of accurate information which, properly examined, and freed from anecdote and conjecture, can be made to reveal matters of profound scientific value It is true that their interpretations may not, and usually do not, coincide with our own, but the extent of their knowledge of the habits of the commoner beasts and birds is astonishing They may know nothing of mechanisms, but they do know a great deal of the animal as a whole Thus it is that Dr Russell finds himself happy in their company, for he strenuously revolts against the purely mechanistic view and pleads for a return to the Aristotelian approach, according to which life and mind are regarded as continuous one with the other, the basis of the zoological system being the form and the behaviour of the animal as a single entity.

The author strongly emphasises the value to science of recording as fully as possible the normal everyday activities of animals, especially in the wild, of describing the objective facts in the simplest and most comprehensive way, disregarding all speculation about the animal's inner life, and studying only the overt and visible actions. Dr Russell teaches that behaviour is always directed toward some definite end, and is largely determined by its result, the action continuing until the goal is reached, that behaviour is often active or spontaneous in the sense that it is not a reaction to external stimuli, and that animals perceive an external world of their own Thus, in studying animal behaviour, the first question to be asked is What is the animal trying to do ? The second To what exactly does it respond, that is to say, what does it perceive ? The third How does its behaviour develop through maturation and through experience ? Finally Is the animal's behaviour modifiable or adaptable ?

The book considers these matters in some detail and illustrates the methods of simple, direct observation without theory and without analysis It leaves all questions on mind and matter to the philosophers It is addressed to students of biology and to the general public, and to these it can be strongly recommended Reading this book, one is driven to the conclusion that no zoological curriculum can be regarded as being complete unless it includes a course of animal behaviour given by someone with Dr Russell's knowledge and devotion to his subject

Embryology and Genetics

Embryology and Genetics By Prof T H Morgan Pp viii+258 (New York Columbia University Press, London Oxford University Press, 1934) 15s net

ONE of the most serious gaps in the whole structure of theoretical biology is the lack of connexion between the concepts of genetics and of embryology Both sciences have a peculiar importance for biology because they both deal with their subject matter in a particularly objective way The organism is not analysed along any of the lines worked out by the older physical sciences, but the path of analysis grows directly out of the reactions which are observed In this respect, genetics has been conspicuously successful, so that we can now, theoretically at least, represent an organism symbolically as a set of genes In practice, we cannot give a completely sufficient representation of an organism in this way, but we can often state precisely the way in which it differs from its fairly near relatives It is as though we knew the active groups of a complex organic molecule, but not the molecular nucleus

In genetics, one gene stands symbolically for a whole series of developmental stages, so that it may be said to determine a red eye at one stage, for example, and a black eye at another, like some of the genes discovered by Huxley and Ford in

Gammarus It should be the province of embryology to lay bare the basis of such series and to find how genes interact to produce their final effects This involves an analysis of the whole process by which a complicated adult organism is developed out of an apparently simple egg-cell, and has been found to be an extremely difficult task. As yet, experimental embryology has been chiefly concerned with the blocking in of the main features of the future organism, and has found itself dealing with characters which are not much affected by the genes described by geneticists, characters in fact which, to pursue the analogy mentioned above, seem to depend on the molecular nucleus in the formula for the organism

There could be no one more fitted to explain the importance of these matters than Prof Morgan, who is at once a well-known experimental embryologist and the foremost geneticist of his time His book should appeal to a wide public, since although not entirely popular, it is written in a way which makes it comprehensible to scientific workers who have not previously taken particular interest in the questions under discussion A general reader will find here one of the most lucid summaries of experimental embryological research into such questions as the development of isolated blastomeres or egg fragments, or the artificial production of twins The results of these inquiries cannot easily be summarised, and an account of them therefore occupies more space than need be devoted to the clear-cut results of genetical experiments, which have led to a very few generally applicable hypotheses

The confused mass of data obtained by the older experimental embryology is at last beginning to be put in order under the influence of the recent work of Spemann, who registered the first success in the attack on the fundamental problem of embryology This problem is, I take it, the question of why a given part of the embryo develops into a given part of the adult, and Spemann's answer, that it does so because it is stimulated to do so by an organiser, is only the first crude beginning of the analysis, comparable to saying that a muscle contracts because it is stimulated to do so by a nerve But crude though it may be, it is the best we can do as yet The importance of having any answer at all, even if we have some doubts as to how widely it can be applied, is so great that it is primarily in connexion with these theories that we shall have to examine the relevance of the ideas of genetics

Prof Morgan, by a self-denying ordinance, rigidly denies himself all speculation on this subject, but indications are not lacking that it will soon be possible to attack the problem. Already there is the significant fact that when an organiser induces an organ, the reacting tissue develops its own peculiar specific characters Seidel's demonstration that the activity of the *Bildungszentrum* in the insect egg depends on the interaction of the nuclei and the cytoplasm is another hint We already know something about the action of genes which affect some of the better understood biochemical systems, such as the system which leads to the formation of pigment in some animals It is probably not too much to hope that our knowledge of the chemistry of organiser action will soon develop to a similar level But as yet we have no idea how to explain the action of genes which determine pattern Some aspects of this, the most difficult problem of morphology, are considered fairly fully by Morgan, who gives us two chapters on the production of two embryos from one egg, or one embryo from two eggs These two chapters, like the rest of the book, raise in a most fascinating way a series of important problems, at the answers to which Prof Morgan is too cautious to guess in our present state of ignorance

C H WADDINGTON.

Photo-electric Cells and their Applications

Photoelectric Cells their Properties, Use and Applications By Norman Robert Campbell and Dorothy Ritchie Third edition Pp vii+223 (London Sir Isaac Pitman and Sons, Ltd , 1934) 12*s* 6*d* net

THE third edition of this book is, as its authors point out, practically a new book altogether, though certain portions of the previous editions are retained without much alteration The differences arise not so much from the new material which has become available since the last edition was issued—though this is considerable—as from a change in the balance of the treatment, and in the class of reader for which the book is intended. It is now less of a handbook for those who actually want to use photo-cells, or a textbook on the theory of the photo-electric effect, than a book for those who might want to use them, and do not object to a somewhat abstract method of treatment

This edition is divided into three sections, dealing respectively with the properties, methods of use, and some of the applications, of photo-cells The first section is that which differs most from the last edition It starts with a moderately full, though not mathematical, account of the theory of the internal and external photo-electric effects and of rectification at thin films, based on the idea of stationary states for the 'free' electrons in metals and semi-conductors This is followed by full and clear accounts of the properties of vacuum

and gas-filled emission cells, of rectifier and of conductivity cells These are accompanied by a large amount of illustrative data given in the form of diagrams

The next section deals in a moderately detailed way with the manner of using photo-cells It starts with an abstract account of the principles of measuring instruments with special reference to photo-cells This is followed by two chapters on the measurement of the small currents which arise when the photo-cells are used with light of low intensity, and with valve amplification of the output from a photo-cell The modern four-electrode electrometer valve has replaced the valve bridges previously described, and mention is made of the use of the galvanometer in ballistic fashion The final chapter deals mainly with 'ticker' methods of measuring the current

The final section is called "Some Applications of Photoelectric Cells", and is the least satisfactory part of the book in that it gives the impression of being merely the summary of a much more extensive treatment of the various branches of photometry by means of photo-cells (May we hope for such a treatment as a separate book in the near future ?) It gives, however, a useful comparison of many ways of using these cells for the measurement of light intensities

The book is not quite free from misprints and slips of the pen, but these are few The printing and paper are an improvement on those of the last edition

Short Notices

Die Dreielektrodenröhre und ihre Anwendung Übungen an der Dreielektrodenröhre mit den zugehörigen theoretischen Erläuterungen Von Dr Friedrich Moeller (Abhandlungen zur Didaktik und Philosophie der Naturwissenschaft, Heft 15) Pp vii+155. (Berlin Julius Springer, 1934) 9 60 gold marks.

DR MOELLER's book is designed for students, and it is a recommendation that it deals with the subject from both the theoretical and practical points of view. The object of the author is set out in his foreword . " the theoretical portion of the book can be looked upon as a text-book of the electron-valve, which attempts to explain the simpler problems of valve-theory without the necessity for special prior knowledge of A C technique"

The subject matter is divided into five main parts, and these are subdivided into 'Theory' and 'Practical' The parts deal with (1) the valve itself, and its properties, giving the definitions of 'slope', *Durchgriff*, etc , (2) triodes with resistance anode loads—amplification and power output , (3) triodes with tuned circuits, including H F amplification and self-oscillation , (4) modulation ; and (5) demodulation

It is felt that the author has undertaken a very difficult task in attempting to cover satisfactorily the theory of all this ground even to the extent required for a textbook of the triode for students, in a book of 150 pages , and when, in addition, space is allotted to practical experiments, some omissions are inevitable. Thus, although the book does cover a large part of the ground in a very thorough way (often, we feel, too thoroughly), a number of important problems are omitted or dealt with very briefly, and one is often left with a feeling of incompleteness The practical considerations are not always dealt with in the best way, and often digress into further theory.

Nevertheless, judged by the amount of information that has been included, the omission of advanced mathematics, and the suggestions for practical confirmation of results, the book should form a very useful addition to the series of scientific textbooks of which it forms the fifteenth volume, and should provide a good starting point for a radio student

The phraseology of the book is moderately straightforward, and anyone with a fair knowledge of the German language should have little difficulty in reading it, though the reasoning often seems unnecessarily involved, and the methods rather cumbersome Its value as a textbook and more so as a reference book would be improved by the addition of bibliographical references, there being at present only some half-dozen, and these to other volumes of the same series

Handbuch der Biochemie des Menschen und der Tiere Herausgegeben von Prof Dr Carl Oppenheimer Zweite Auflage Ergänzungswerk, Band 2 Pp xix+961 (Jena Gustav Fischer, 1934) 71 gold marks

IN a review of the last published supplementary volume to this work—1154 pages, in two half volumes, bringing vols 1, 2 and 3 of the second edition of the "Handbuch" up to the end of 1932—it was stated (NATURE, 133, 595 , 1934) that the volumes were of the type that filled "the user with awe-inspired gratitude and the reviewer with awe-inspired terror" A similar effect is produced by the second supplementary volume , it brings the main vols 4, 5 and 6 up to, presumably, the same date ; it occupies, with its index, nearly 1000 pages ; and it is apparently just within the 'single volume' limit

This makes it somewhat unwieldy, as well as somewhat unviable in the unbound form Still, the names of some of the contributors, Profs L Pincussen, J. Wohlgemuth, W. Grimmer, A. Scheunert, E Grafe —to select at random a few, none of whom contributed to the first supplementary volume—will almost certainly secure that the possessors of paper-bound copies hasten to get a volume of such obvious value put into boards as quickly as possible

The contents of this supplementary volume are divided in the following manner The supplement to vol 4 is concerned with the chemistry of tissues and organs, including blood and lymph, skeletal and epidermal structures, muscle, the apparatus of circulation and respiration, the nerves and sense organs, and the chemistry of tumours The supplement to vol 5 deals with the glands and secretory organs, which are classified into those involved in digestion and those involved in reproduction The supplement to vol 6 covers the general field of nutritional processes, including digestion, absorption and excretion Finally, vol 7 is brought up to date under the sub-headings of nutrition, gas exchange and general metabolism

It is clearly impossible to do more than indicate here in a quite general way the field surveyed in this book, the largeness of the field is in itself a measure of the vastness of territory mapped in the original work to which this is the second supplementary volume A L B

Radio round the World By A W Haslett Pp vii+196+7 plates (Cambridge At the University Press, 1934) 5s net

THIS volume presents an interesting account, in a form suitable for the layman, of the main facts accompanying the application of electric waves to radio communication A brief, historical account of the earliest discoveries of these waves includes a reference to the doubts and difficulties which accompanied the pioneer workers of some thirty years ago The story of the propagation of electric waves of all lengths round the world, by the aid of the ionised layers in the earth's atmosphere, is then developed in a straightforward and skilful manner A chapter entitled "The Sun calls the Tune" is noteworthy in this portion of the book, and directs attention to the various ways in which the possibilities of long distance radio communication are controlled or limited by solar influence

Later chapters utilise an account of the trend of modern developments to indicate the future possibilities of radio technique, particularly in the application of ultra short waves to secret communication for war purposes, to television, and, by no means least important, to the introduction of a new phase of curative medicine

On the whole, the author has obviously taken a good deal of trouble to get his facts correctly stated, although p 160 contains, in a loosely worded sentence, a bad misrepresentation of the possibilities of radio direction finding. A reviewer in another country might complain that in certain portions of the book undue stress is placed upon recent British work in radio research ; while in other places, the author has omitted to mention the Radio Research Board, from the publications of which so much of the material has obviously been derived These are, however, minor blemishes in an otherwise successful effort to show the general reader how very much more there is in the science and practice of radio communication than the mere dissemination of broadcast programmes.

Annales Bryologici a Year-Book devoted to the Study of Mosses and Hepatics. Edited by Fr Verdoorn Supplementary Vol 4 : *Studien uber Asiatische Jubuleae (de Frullaniaceis 15–17) mit einer Einleitung Bryologie und Hepaticologie, ihre Methodik und Zukunft* Von Fr Verdoorn Pp viii+231 (The Hague Martinus Nijhoff, 1934) 6 guilders

A SKETCH of the progress of hepaticology occupies the first thirty six pages, a knowledge of early authors is considered essential in questions of nomenclature and in dealing with types of genera, Evans, Howe, Lindberg, Schiffner and Spruce are authors favourably mentioned, but Stephani's "Species Hepaticarum" is very frankly criticised, its errors and other faults are considered to be so grave, that setting it aside as "opus excludendum" is discussed, in view however of its wide acceptance, that course is inexpedient and revision is recommended Improved methods, geographical, cytological, genetical, experimental morphological, etc, are urged in the study of liverworts, the weakness of much recent bryological literature is referred to Revision is the most urgent need of to-day, progress will largely depend on the study of the smaller groups, which are insufficiently understood

De Frullaniaceis xv xvii (pp 40 224) carries on work published in earlier supplements Dealing with the Lejeuneaceae, original diagnoses are reproduced as being often inaccessible to workers in Asia, there is a clavis to the fourteen genera, with notes on variability distinguishing characters, distribution and stations Section xvi is a revision of the Asiatic Tamarisceineae, a restricted but definite specific value is given to the Ocelli and a clavis to the six Asiatic species relies upon characters of the lobi, amphigastria and ocelli Section xvii deals with some recent collections and the distribution of Indomalayan Frullaniaceae and Holostipae

Strahlung und Lichterythem Von K W Hausser und seinen Mitarbeitern Herausgegeben von C Ramsauer und R. Kollath (Ostwald's Klassiker der exakten Wissenschaften, begrundet von Wilhelm Ostwald, neu herausgegeben von Wolfgang Ostwald, Nr 239) Pp iv+89 (Leipzig Akademische Verlagsgesellschaft m b H, 1934) 4 gold marks

THOSE who knew the late Dr Hausser will find much pleasure in the fact that the memory of this brilliant young physicist, who died in 1933 at forty-six years of age, is honoured by the publication of his original papers on the action of sunlight on the human skin as one of "Ostwald's Klassiker" Hausser was a pioneer in this branch of biophysics, for he was the first to realise the importance of using monochromatic light of measured intensity in the investigation of the causes of erythema and sunburn, by means of his large quartz prisms He was responsible for the discovery of the fact that the human skin is particularly sensitive to two regions of the violet portion of the spectrum, one of which is normally absorbed by the atmosphere All interested in biophysics would do well to possess this little book

Radioactivity: Old and New*

By the RIGHT HON LORD RUTHERFORD, O M, F R S

I WAS much honoured by the invitation to give the first course of the Joly Memorial Lectures As is well known, Joly was for many years not only intensely interested in the problems of radioactivity, but also made numerous original and important contributions to our knowledge of this subject When the large and continuous emission of heat from the radioactive bodies was made clear in 1903, Joly's alert and original mind was at once attracted to the problem of the effect of this steady generation of heat by the radioactive bodies present in the earth's crust on the geological history of our planet To obtain reliable data, he devised simple but ingenious methods for measuring the amount of the primary radioactive bodies, uranium and thorium, in typical rocks constituting the earth's crust He was the first to point out the far-reaching significance of this small but steady supply of heat on the internal temperature gradient of the earth, resulting in violent movements in the earth's crust Indeed, he was of opinion that the rise and fall of continents and the elevation of mountain chains were intimately connected with the heating effect of radioactive bodies over long intervals of time A fascinating account of these bold and original ideas has been given by Joly in his books and papers

Of all the contributions made by Joly in the field of radioactivity, the discovery of the origin of the pleochroic haloes, observed in certain kinds of mica, has left the strongest impression on my mind It required not only an acute and original mind but also a touch of real genius to connect these minute haloes, the origin of which had long been a mystery, with the effects of radioactive transformations Joly, as the result of an intensive investigation, was able to prove that the darkening of the mica halo was due to the α-particles liberated over ages from a minute inclusion containing either uranium or thorium In a well-developed halo, a series of rings was observed, each of which corresponded in radius to the range of one of the groups of α-particles liberated from the radioactive material. In this way, he was able to show that the processes of radioactive transformation were the same hundreds of millions of years ago as to-day In some very old micas, Joly observed an inner ring corresponding to α-particles of much shorter range than any observed from the known radioactive bodies To account for it he postulated the earlier existence of an unknown radioactive element which he provisionally named 'hibernium' The researches of Hevesy in the last few years indicate that this ring is probably due to a known element, samarium, which has recently been found to be weakly radioactive These haloes are produced by an exceedingly minute quantity of uranium or thorium as in inclusion in the mica Probably the emission on an average of one α particle every one hundred years continuing through geologic ages would give rise to a discernible halo

I could give many more illustrations from other fields of inquiry which equally show that Joly possessed to a marked degree that rare quality of originality and vision characteristic of the greatest investigators of the past

The property of spontaneous radioactivity is shown to the most marked extent by the heaviest elements, uranium and thorium, and the products which arise from their transformation Only a few lighter elements show this property and those only to a feeble degree We now know that the property of radioactivity is a sign of the instability of the atoms concerned Take, for example, the best known radioactive element, radium For some unknown reason, each second a minute fraction of the radium atom becomes unstable and breaks up with explosive violence, a fragment of the atom—an α-particle—being hurled out with high speed As a consequence of these atomic transformations, a new type of atom is formed—the radium emanation—which in turn is unstable, breaking up rapidly with the liberation of an α-particle The process of transformation once started proceeds through a number of successive stages, finally ending in the formation of a stable and non-radioactive isotope of lead The successive transformations of uranium lead to the formation of twelve distinct types of radioactive element. and in all more than thirty of these radioactive elements are known Each of these elements suffers transformation according to a definite law but at a different and characteristic rate For example, radium is half transformed in 1600 years, the radium emanation in 3 82 days, and its succeeding product radium A in 3 minutes

In most of the transformations, α-particles are alone expelled, but in a few cases the transformation is accompanied by the expulsion of β-rays, which are swift electrons The mass of the atom is not sensibly changed by the expulsion of such a light particle, but the properties of the resulting atom are entirely changed There is one important feature which distinguishes β-ray from α-ray transformations; all the α-particles escape with

* From the first Joly Memorial Lecture delivered at Trinity College, Dublin, on January 23, 1935

identical speed and thus the transformation of each atom leads to the liberation of an equal quantity of energy. In the case of a β-ray transformation, one β-particle is expelled per atom, but the speed of the β-particle varies widely from atom to atom. If this be the case, one atom loses more energy than another, and we should consequently expect the energy content of the new atoms formed to differ. There is, however, no evidence that such differences of energy exist, and indeed when an α-ray body is formed by a β-ray transformation, the α-particles are again expelled with identical speeds. This difference between α- and β-transformations raises great difficulties and no satisfactory explanation is as yet forthcoming. It has been suggested either that the conservation of energy cannot be applied to such β-transformations, or that some of the energy from the atom is carried off in the form of an undetectable particle of very light mass called the 'neutrino'. We shall see that the same problem arises in the transformation of radioactive bodies which can be produced by artificial methods.

It is desirable at this stage to say a word about the nuclear structure of atoms. At the centre of each atom is a minute but massive nucleus which carries a resultant positive charge. This charge controls the number and arrangement of the electrons which surround the nucleus. The properties of an atom are thus defined by a whole number which represents the number of units of charge carried by the nucleus. This fixes the number and order of the elements, but we now know that there are many species of the same element, defined by its nuclear charge, which have different masses. The number of these isotopes of an element varies; some elements like aluminium are apparently simple, but others like tin have a dozen isotopes varying in mass over a wide range.

The appearance of radioactivity results from the spontaneous transformation of the minute nucleus of an atom. The expulsion of an α-particle carrying two positive charges lowers the charge on the nucleus of the residual atom by two units, while the expulsion of a β-particle raises it by one.

If we are to effect the transformation of an element, we must in some way alter its mass or its charge. This can be done by adding or subtracting a particle, whether charged or uncharged, from the nucleus. This is easy in imagination but difficult in practice. The most effective way so far found is the bombardment method, involving the entry of a foreign particle into the structure of the nucleus and in some cases leading to the loss of a charged particle from the nucleus. We shall illustrate these different types of transformation by considering a few of the simpler typical cases.

The first proof of the artificial transformation of an atom was given in 1919, when it was found that the bombardment of the gas nitrogen by fast α-particles gave rise to the liberation of a number of fast protons which could only come from a disintegration of the nitrogen nucleus. It is now clear that about one α-particle in 100,000 comes close enough to a nitrogen nucleus to enter its structure. The α-particle is captured and momentarily forms a new nucleus of charge 2 units higher and of mass 4 units greater. This newly formed nucleus is unstable and breaks up with explosive violence, expelling a proton in the process. The mechanism of the reaction is given below

$$_{7}N^{14} + {}_{2}He^{4} \longrightarrow {}_{9}F^{18} \longrightarrow {}_{8}O^{17} + {}_{1}H^{1}$$

The resulting stable nucleus is an isotope of oxygen of mass 17, which we now know to exist in small quantity in ordinary oxygen. About twelve light elements can be disintegrated by α-particles, and in all cases protons of characteristic speeds are emitted; the general mechanism of the reaction is probably similar, leading in all cases to the emission of a proton and the formation of a new but stable nucleus of mass 3 units greater.

During the last few years, another important type of transformation has been brought to light in which a new and strange type of particle called the neutron is expelled. The neutron, as its name implies, carries no electric charge, but has a mass about equal to that of the proton. Since it has no charge, it does not ionise the gas in its path and consequently shows no track in an expansion chamber. At rare intervals in its passage through a gas, it hits the nucleus of an atom in its path and shoots it forward with high speed. This struck nucleus is charged and ionises the gas, so that its track through the gas is shown in a cloud chamber. While these 'knock-ons' are comparatively rare, they form a very convenient method of detecting the presence of the invisible neutron and forming an idea of its velocity. One of the best ways of producing a supply of neutrons is to bombard the element beryllium with fast α-particles. The α-particle is captured and the resulting nucleus of carbon 13 breaks up into a carbon nucleus of mass 12, while a fast neutron is expelled. The mode of the reaction is shown below

$$_{4}Be^{9} + {}_{2}He^{4} \longrightarrow {}_{6}C^{13} \longrightarrow {}_{6}C^{12} + \text{neutron}^{1}$$

We are now able to produce neutrons in a variety of ways, not only by the action of α-particles, but also by bombarding different elements by protons and deuterons.

Still another striking type of transformation can be produced by α-particles, resulting in the artificial production of new radioactive bodies. In the transformations previously considered, the

residual nucleus is a known type of stable nucleus, and is non-radioactive. A radioactive nucleus is an unstable type of nucleus which breaks up with the emission of fast particles, ultimately forming another stable nucleus. The production of an artificial radioactive body was first noted by M. and Mme. Curie-Joliot by bombarding boron with fast α-particles. After bombardment for a few minutes, the boron continued to show a marked activity for an hour or so after it was removed from the bombarding source. This activity decayed in exactly the same way and according to the same laws as the ordinary well-known radioactive bodies, but the type of particle emitted was quite different. Strange to say, it was found that high-speed positive electrons, or positrons, were emitted, and not α-particles or negative electrons such as appear in the spontaneous transformations of the radioactive bodies uranium and thorium. In order to account for the production of a radioactive element by bombarding boron with fast α-particles, it seems clear that the transformation occurs in two stages according to the scheme below.

$$_{5}B^{10} + {}_{2}He^{4} \longrightarrow {}_{7}N^{13} + \text{neutron}^{1}$$
$${}_{7}N^{13} \longrightarrow {}_{6}C^{13} + {}_{1}\text{positron}$$

In the first stage, the α-particle is captured by the boron nucleus forming an unstable isotope of nitrogen, N^{13}, together with the liberation of a fast neutron. This isotope of nitrogen does not exist in Nature and is transformed slowly into the stable isotope of C^{13} by the expulsion of a positive electron. The activity of the radioactive body N^{13} decays to half value in about 14 minutes. By using the activity of this body as an indicator of its presence, it was shown by chemical methods that the radioactive body was an isotope of nitrogen. In a similar way, by bombarding other elements, radioactive isotopes of phosphorus and silicon could be formed, each with a characteristic period of decay.

This new discovery was rapidly followed up in a number of directions. Prof. E. Fermi and his collaborators in Rome found that a large number of these radioactive bodies could be formed when the elements were bombarded by neutrons derived from the action of α-rays on beryllium. On account of the absence of charge, the neutron is able to enter the structure of even a heavy element, where the α-particle on account of its charge is ineffective. Even the heaviest element, uranium, when bombarded by neutrons, gives rise to at least four new distinctive types of radioactive bodies, with half periods of 15 seconds, 40 seconds, 13 minutes and 100 minutes. The actual nature of the transformations involved has only been studied in a few cases. In all known cases, the neutron is captured; sometimes a heavy particle, an α-particle or proton, is emitted, but generally a higher isotope of the element is formed which may be unstable and emit negative electrons. It is worthy of note that all the radioactive bodies produced in this way break up with the liberation of fast negative electrons and not positive electrons, as in the original cases found by the Joliots. Cockcroft, Lawrence and others have found that bombardment of certain elements by fast hydrogen ions also gives rise in some cases to the production of new radioactive bodies.

It seems clear from these results that we are able greatly to increase our knowledge of the isotopes of the elements. None of these radioactive bodies are found in Nature, but represent unstable types of isotopes with a very limited life. During the last few months, it has been found that the efficiency of the process can be increased in some cases about a hundred times or more by slowing down the neutrons. This can be done by passing them through hydrogen or a solid material like water or paraffin which contains hydrogen.

We have so far spoken of the transformations brought about by the swift α-particles spontaneously expelled from radioactive substances, and the neutrons which arise from the bombardment of certain elements by α-particles. Another notable advance has been made by the use of bombarding particles produced artificially in the electric discharge and speeded up by appropriate methods. This involves complicated apparatus and in general the use of high potentials of the order of one million volts. In this way, copious streams of fast particles can readily be produced, corresponding in number to the α-particles expelled from thousands of grams of radium. Cockcroft and Walton were the first to show that transformation effects on a comparatively large scale could be produced by bombarding light elements like lithium and boron by fast protons. Time does not allow me to consider the mechanism of these transformations, which are different for each isotope of the same element. Transformation only appears to occur when the proton is captured by the nucleus, which then breaks up with explosive violence. Similar but different effects are observed when the ions of heavy hydrogen of mass 2 are used as bombarding particles. I would like, however, to refer to recent experiments in which it has been shown that artificial radioactive elements can also be produced by these new methods. Cockcroft and Walton and others have shown that ordinary carbon, whether bombarded by H^1 or H^2 particles, gives rise to the production of a new radioactive substance which decays to half value in about 11 minutes, emitting positive electrons in the process. It is believed that the

radioactive body formed in both cases is N^{13}, which is transformed into the isotope of carbon C^{13} by the emission of a positron It is not yet settled whether this radio-nitrogen differs from that formed by α-rays, where the half period seems to be longer, namely, 14 minutes

It seems likely that when very intense streams of still swifter particles are available, radioactive bodies of strong intensity may be produced by these artificial methods It may be also that some of the bodies produced in these ways may give rise to a succession of changes such as is characteristic of the heavier elements uranium and thorium

Sufficient, I think, has been said to illustrate the extraordinarily interesting results obtained in this fascinating field of inquiry We can build heavier elements from lighter, and break up other atoms into fragments, and produce novel radioactive elements by the score This new field of what may be called nuclear chemistry is opening up with great rapidity Much work, often of a difficult technical character, will be required to prove the exact nature of any of the transformations which have been observed, but a very promising beginning has been made Future work may disclose many surprises, for new and unsuspected particles may come to light In any event, we are entering a no man's land with the ultimate hope of throwing light on the way atoms are built up from simpler particles

A New "Nomenclator Zoologicus"

FROM the time that the tenth edition (1758) of the "Systema Naturæ" of Linnæus, which established the binomial system, was recognised as the basis of the nomenclature of animals, systematists have always had to face the difficulty of ascertaining what names have been used for genera Since the same name cannot be validly used more than once in the whole of zoology, it is obvious that unless this information is reasonably accessible, many homonyms are inevitably created and themselves add to the confusion Moreover, even when the existence of a name is known, it is often by no means an easy matter to find the original reference to it or to ascertain its position in the animal kingdom Before describing the situation at the present day, it may be as well briefly to review the attempts that have been made to solve these problems

The first Nomenclator to be published was that of Agassiz, which appeared between 1842 and 1846 , it was followed by that of Marschall, which covered the period 1846–68 and was published in 1873. In 1864 there appeared the first volume of the "Zoological Record" which, however, in its earlier years, did not always include an annual list of new genera The names in all these, with many others, were collected together by Scudder, who attempted a list of all published genera from Linnæus to 1879, and his work, which was published in 1882–84 as Bulletin No 19 of the U S National Museum, is the only list of its kind that has yet been completed. It contains about 80,000 names Supplements to Scudder's work are represented by the two volumes, edited by Waterhouse and published by the Zoological Society of London, of the new genera contained in the "Zoological Record" with some additions. These volumes together contain some 62,000 names, and cover the periods 1880–1900 and 1901–10 respectively. The new generic names in the "Zoological Record", which average about 2,000 per annum, have not been collected together since that date

Sherborn's famous "Index Animalium", which was published between 1902 and 1933 and deals with both generic and specific names, though marvellously complete, only goes up to the year 1850 There also began to be published in 1926, under the auspices of the Prussian Academy of Science, an ambitious work entitled 'Nomenclator animalium generum et subgenerum" If circumstances had permitted this to be carried through as originally planned, it would have been a very important contribution to the problem for the period that it dealt with Though it appears to cover the ground with relatively few omissions up to about 1909 and it purports to include all names up to 1922, those dealing with the later years are taken almost entirely from the annual indexes to the "Zoological Record" The choice of the date 1922 was peculiarly unfortunate, because the "Zoological Record" was necessarily far from complete in the War years and those immediately following, with the result that it omits the very numerous names that were actually published during 1914–22 but were only found and recorded afterwards Furthermore, only about three quarters of this German work have yet appeared, although it has been nine years in course of publication Its use is therefore very limited, and it has the added disadvantage of being extremely expensive.

The present position is, therefore, that a systematist who wishes to erect a new generic name finds it almost impossible, even at the expense of much labour, to satisfy himself that any given one has not been used already. Not only are his sources of information very scattered and far from complete, but also many of them are rare and expensive

The Council of the Zoological Society of London has therefore decided to make financial provision for a scheme to produce an entirely new "Nomenclator", in which an attempt will be made to include every generic name used in zoology from 1758 up to and including 1935 It is estimated that this will involve about 190,000 names, of which about 100,000 relate to insects The names from 1758 to 1879 will be given their original references, these being taken, so far as those up to 1850 are concerned, from Sherborn From 1880 onwards, the "Nomenclator" will take the form of an index to the "Zoological Record" itself The class of animal concerned, or in the case of insects, the order, will also be given

A very intensive search is being made of the literature to discover names that have been omitted from existing records, and this has already resulted in the discovery of some seven hundred in insects alone, chiefly among publications that appeared between 1900 and 1920 It is hoped also to enlist the aid of all systematic zoologists throughout the world in making the work as complete as possible, and a circular asking for their help is being sent out In the course of this, they are asked to send details of any generic names, with their original references, to Dr S A Neave, of the Imperial Institute of Entomology, 41 Queen's Gate, London, S W 7, who is supervising the undertaking on behalf of the Zoological Society of London, and will also have the assistance, in particular groups, of experts at the British Museum (Natural History)

It is hoped that the work may be completed for publication about the end of 1937, and that it will be found possible to issue it at a moderate price

Solid Carbon Dioxide

IT is just a hundred years ago since carbon dioxide was first solidified by Thilorier Most chemists are familiar with carbon dioxide 'snow', which has long found use in the laboratory as a convenient means of producing temperatures down to about $-80°$ C The comparatively small quantities required for such purposes were obtained by the simple but wasteful method of allowing liquid carbon dioxide from a cylinder to expand through a valve into a collecting bag , in these circumstances less than 30 per cent of the weight of the liquid used is obtained in the form of 'snow'

Until about ten years ago, the solid was only used as a laboratory freezing agent, and also in small quantities medically as a cauterising agent For the latter purpose the 'snow' was usually pressed into a solid pencil in a mould, making it more convenient to handle, and, owing to the reduced surface exposed, less rapid in evaporation

The commercial development of the manufacture of solid carbon dioxide became a possibility only when refrigeration began to play a large part in the organisation of food supply. A great impetus was given by the rapid growth of the ice-cream industry in the United States, where the annual production (under the familiar name of 'dry ice') rose from a few tons in 1925 to approximately 27,000 tons in 1933. In Great Britain, production on a large scale commenced several years later, but it is estimated that the output in 1934 reached 10,000 tons, and demand for the product continues to expand.

In Great Britain, the gas for the production of solid carbon dioxide is chiefly derived as a by-product from industrial processes, such as the manufacture of synthetic ammonia, and in the production of alcohol Purification in greater or less degree depending on the source of gas is required in all cases, including the removal of odoriferous compounds and of inert non-condensable gases which, under certain conditions, and if present in sufficient quantity, would render the liquefaction of the carbon dioxide difficult or even impossible Following liquefaction of the gas, solidification may be brought about by various processes These, while relatively simple, are very interesting from the physico-chemical point of view , and their development on the most economic lines has been the result of much research on the phase rule and thermodynamic aspect of the system The process most commonly adopted is to allow the liquid to expand in suitable chambers with the formation of gas and 'snow', the latter being pressed into blocks of convenient size and shape, and the gas being returned for recompression In another process, the liquid carbon dioxide is expanded in chambers at a pressure just below that corresponding to the triple point, and solid blocks are obtained without the use of a press, while according to a third process the liquid is frozen in moulds by the rapid evaporation of liquid ammonia As might be expected, the several processes differ considerably in thermodynamic efficiency, although this is not reflected appreciably in the cost of production, power costs being only a small fraction of the whole

Solid carbon dioxide in its commercial form is available in blocks of cylindrical or rectangular section, weighing approximately 25 lb. These blocks have the appearance of highly compressed snow and may be cut without difficulty by means

of an ordinary saw The temperature of the solid under a pressure of one atmosphere of carbon dioxide is -78.9° C., but when exposed to the atmosphere is somewhat lower owing to the reduction of partial pressure of carbon dioxide near the surface of the block On account of the low temperature, gloves should always be worn when handling the solid In a still atmosphere, a block of the solid evaporates more slowly than might be expected, mainly on account of the low conductivity of the enveloping film of gaseous carbon dioxide and of the high latent heat of sublimation of the solid (137 cal./gm at -78.9° C.) Thus a 25 lb block requires about 24 hours to evaporate completely

The most careful measures have to be taken to prevent needless waste by evaporation both in storage and transport, and to this end heavily insulated storage bins have been designed in which the evaporation loss has been reduced to 0.5 per cent a day, while the evaporation in large railway transport containers is of the order of only 2 per cent a day Research into the most suitable types of container and insulating material has led to the development of a range of packages suitable for the transport of solid carbon dioxide, which enables this product to be sent from the producing centre to depots in all parts of the country, and thence to the user, with a very small total loss Although the solid can be stored for very long periods without serious loss, it has been found that a limit is set by the slow growth of the crystals, which tends to produce disintegration

As might be expected, the principal uses for solid carbon dioxide are in connexion with refrigeration Its dryness, high latent heat and high density (1.4) render it attractive in many cases where the cost of removing heat units is not the only consideration As already stated, the ice-cream industry was the first to adopt this refrigerant on a large scale in place of ice and salt mixtures, and the requirements of this industry continue to expand

A considerable field exists for solid carbon dioxide in connexion with the transport of perishables, such as meat, fish, fruit and flowers, where controlled temperature conditions are required As a result of the work which has recently been carried out under the auspices of the Department of Scientific and Industrial Research at Cambridge and at the Torry Research Station, and by other investigators, it is now known that carbon dioxide inhibits, in a marked degree, the growth of many of the bacteria and moulds which are largely responsible for the deterioration of meat and fish, so that the value of solid carbon dioxide as a refrigerant and preservative is further enhanced on this account. In preserving flowers, however, the effect is one of arrested metabolism due to the low temperature and the presence of carbon dioxide

It may be remarked that, although the successful utilisation of solid carbon dioxide as a refrigerant presents no serious technical difficulties, care must be taken in the design of equipment such as ice-cream conservators, refrigerated transport containers and the like, if this refrigerant is to be used successfully and economically

Except where the low temperature of solid carbon dioxide is specially required, means must be taken to reduce the heat flow to the refrigerant, and this can be done conveniently by interposing thermal insulation between the refrigerant and the cooled chamber A number of other methods employing a secondary liquid are available.

Reference has already been made in NATURE (Oct 6, 1934, p 529) to the use of solid carbon dioxide in the assembly of machine components by means of shrink fits The effect of the low temperature in contracting metal parts is best attained by immersing the parts in a suitable low freezing point liquid containing solid carbon dioxide In this way rapid and uniform cooling results The advantages of this method of shrink fitting are that it enables small components, such as cylinder liners, sleeves and valve seats to be readily inserted into housings without the use of a press, thereby obviating the possibility of distortion, and that the structure of heat-treated parts is not disturbed as might be the case with hot shrinking Solid carbon dioxide is already being used in Great Britain in the production of automobile and aero engines, locomotives and machine tools, and this application is likely to expand considerably as it becomes more widely appreciated

The use of solid carbon dioxide as a convenient means of obtaining a supply of the liquid or gas was first realised by Elworthy who, in a patent obtained in 1898, discussed the economic advantage to be gained from handling carbon dioxide in the solid form instead of as a liquid in heavy steel cylinders. It is only recently, however, that these advantages have been secured as a result of the development of solid carbon dioxide for refrigerating purposes, and the design of suitable containers and other apparatus. Pressure vessels ('liquefiers') are now available which enable the solid to be readily converted into liquid or gaseous form, and the use of solid carbon dioxide for purposes other than refrigeration is rapidly expanding. Foremost amongst these uses must be placed the carbonation and mechanical handling of beverages for which, it is needless to say, only solid carbon dioxide of the highest purity can be employed. For example, in 'Drikold',

manufactured by Imperial Chemical Industries, Ltd., organic esters and sulphur compounds are reduced to less than one part per million, and any oil which may be carried over from the compressors is carefully removed in order to obtain a sufficiently pure product. The solid is also finding increasing use as a source of carbon dioxide for the production of salicylic acid and other chemicals.

Passing reference only has been made to some of the principal uses of solid carbon dioxide. Certain other applications are still in the development stage, while others are constantly being discovered. The development of the industry has been very rapid and constitutes one of the most remarkable modern examples of the application of scientific methods to industrial requirements.

Obituary

Prof. Arthur Thomson

On his retirement in 1933, Prof. Arthur Thomson, whose death on February 7 will be widely regretted, had completed a somewhat unusual record of academic service. He was born on March 21, 1858, and for forty-eight years he represented human anatomy at the University of Oxford, first as University lecturer in human anatomy and afterwards as Dr. Lee's professor of anatomy. After serving an apprenticeship in the famous school of anatomy at Edinburgh under Sir William Turner, Thomson went to Oxford in 1885. Unlike many of his later contemporaries, he did not enjoy the advantage of stepping into a department already equipped for teaching and research. On the contrary, the task fell to him of building up a new department from its very foundations. It will readily be appreciated that Thomson's energies were fully employed for a number of years in developing the teaching side of his department to a level appropriate to the medical faculty of the University of Oxford, a task which was rendered very laborious at first by the criticism and opposition of some members of the University who were less ready to appreciate the importance of catering for an extensive and detailed medical curriculum.

Arthur Thomson's own contributions to scientific literature can be divided quite sharply into separate categories. Of these, his papers dealing with the racial variations of the skeleton are the most noteworthy. In this work he was clearly influenced by his late teacher, Sir William Turner, who had stimulated considerable interest in racial anatomy by his studies of the human skeleton in the *Challenger* Reports. Thomson's work on this subject was characterised by the fact that he constantly sought to explain by reference to habits of life and environmental influences the osteological variations which were being at that time recorded by anatomists. He was not content simply with measurements and with the construction of indices, and he was evidently reluctant to accept metrical variations of the skeleton as necessarily of real morphological significance in the assessment of racial affinities. In 1889 he showed the importance of considering posture as a factor in the determination of the proportions and contour of the lower limb skeleton and directed attention to the 'squatting facets' on the tibia and talus. In the same year he published an anthropometrical study of the Veddahs of Ceylon. His interest in craniology led him to investigate the significance of cranial indices which were then assuming such importance in the eyes of the anthropologist. By ingenious models he sought to show that the proportions of the calvarium must be directly influenced by brain volume and by the action of the temporal muscles. These observations were published in the *Journal of the Anthropological Institute* in 1903, and his conclusions, which were admittedly tentative, have in some part been substantiated by statistical study on a larger scale.

In 1913, Thomson made a valuable communication on the correlation of isotherms with variations in the nasal index. Ten years later, this observation was submitted to statistical analysis by him in collaboration with Dr. Buxton, with the noteworthy conclusion that a platyrrhine nasal index is associated with a hot moist climate and a leptorrhine index with a cold dry climate. Other studies by Thomson in this line include a comprehensive study with D. Randall MacIver of Egyptian crania, published in 1905 by the Clarendon Press under the title of "The Ancient Races of the Thebaid", and a paper on the genial tubercles of the mandible in 1915. At Oxford, Thomson will be particularly remembered with gratitude for the part he played in instituting and organising the regular course of study for the University diploma in anthropology, a course which has met with increasing success since its initiation in 1907.

Thomson was a close personal friend of the late R. W. Doyne, who founded the Oxford Ophthalmological Congress, and undoubtedly it was this friendship which led him to make special studies of the anatomy of the eye. This resulted in the publication of two papers on the filtration angle of the eye in 1910 and 1911, and in a brochure on the anatomy of the human eye together with an atlas of stereoscopic photographs of dissections of the eye.

Thomson's last work was concerned with the microscopic structure of the human Graafian follicle and the maturation of the human ovum. These provided the subjects for two papers in the *Journal of Anatomy* in 1919.

Apart from his work at the University of Oxford, Thomson occupied the position of professor of anatomy at the Royal Academy, to which he was elected in 1900. In this sphere he was able to give full expression to his own artistic propensities, and he left an appropriate memorial of his contribution to art in his book "Anatomy for Art Students" which has passed through a number of editions.

Prof J. Macmillan Brown

We regret to record the death of Prof. J. Macmillan Brown, chancellor of the University of New Zealand, and well known as an authority on the peoples of the Pacific, which took place at the age of eighty-nine years, at Wellington N Z, on January 18

John Macmillan Brown was born at Irvine, Scotland, in 1846, the son of Mr James Brown, shipmaster, and was educated at the Irvine Academy, the University of Glasgow, and Balliol College, Oxford, of which he was an exhibitioner In 1874, on the establishment of Canterbury University College, he went to New Zealand to take up the appointment of professor of classics, and later became professor of English literature In 1877 he became a member of the Senate of his University, and in 1923 was elected chancellor, an appointment which he held until his death

Macmillan Brown was best known in England for his work on the problems of the Pacific, and more particularly for his somewhat speculative theories on the origin of the Polynesians and of the remarkable artistic products of Easter Island His views were set forth in considerable detail and fully argued in his books "Maori and Polynesian", "The Riddle of the Pacific" (1924), and "Peoples and Problems of the Pacific" (1927) In the view put forward in the "Riddle of the Pacific" he argued that the famous statues of Easter Island are the product of workers on what was a mausoleum for a circle of islands, which have since disappeared owing to volcanic action. His theories of the peopling of the Pacific, which proved stimulating, if not entirely acceptable, brought the Polynesians as a Caucasic element from Asia, a primeval form of Indo-European. Whatever may be the ultimate verdict on his philological and ethnological theories, they undoubtedly had a stimulating effect in promoting the study of the peoples of the Pacific in New Zealand

Mr Francis J Blight

Old scientific friends of Mr Francis J. Blight will learn with much regret of his death at the age of seventy-seven years, on January 27 at his home at Mill Hill Previously to 1927 he had been closely associated with Messrs Charles Griffin and Co, Ltd., the well-known publishers of technical scientific books, and since 1899, when Miss E. E. Griffin died, he had been chairman and managing director of the firm, only retiring in 1927 in consequence of rearrangements following on the death of Miss Helen Griffin

In early life, Blight, whose father and grandfather had been booksellers and stationers, had been for some years engaged in office work connected with iron and steel works, railway and other architecture, map-making, etc. He had thus become an expert draughtsman, with a wide knowledge of technical processes of many different kinds In 1886 he became assistant manager to Messrs. J and A Churchill, the medical publishers, and in 1894 manager for Messrs. Griffin, then under the able chairmanship of Miss E. E. Griffin Quickly realising the wide need for technical scientific books of all kinds, he developed this side of the firm's business with extraordinary energy and success, bringing out textbook after textbook which had large sales

It was to a very great extent Blight's own personality that led to these books being written He not only suggested them in many cases to men who, he saw, were likely to write them well, but also in their actual production was extremely helpful, particularly perhaps as regards the illustrations It was an extraordinary stimulus and encouragement to meet him, as the writer of this short notice often did, in the well known room at Exeter Street which was pervaded by his genial presence

In 1920 a volume was published in celebration of the centenary of the Griffin firm, which had originated early last century at Glasgow This volume contains sections dealing with the more recent publications of the firm in scientific technology, and written by Prof. Barnett, Sir T Hudson Beare, Sir W. S Abell, Prof W. Gowland, Prof Henry Louis, and other well-known authors In a foreword to the volume, Lord Moulton stresses the national importance of technological publishing, and remarks that to Mr Blight "the exceptional prosperity of the Firm, and its services to the country during the late war, must be primarily ascribed"

Only brief mention can be made here of another side of Blight's life He was a keen supporter of the Baptist Church, and particularly of its charitable activities with respect to children and young persons He also strongly supported all that has been done in this direction by State action and municipal activity He was a man of simple character, in which love of his fellow men was never overshadowed by either business or scientific interests J. S H

Mrs Jane Longstaff, who died on January 19, aged seventy-nine years, contributed important papers on Palæozoic gastropod shells to the *Quarterly Journal of the Geological Society*. She was the widow of Dr G. B Longstaff, a well-known entomologist, with whom she shared a wide interest in natural history She was a fellow of the Linnean and Geological Societies, and was for some time a member of council of the Palæontographical Society Her early writings were published under her maiden name of Jane Donald, and the value of her researches was acknowledged so long ago as 1898, when the Geological Society awarded her its Murchison Fund

---

We regret to announce the following deaths

Mr J. H Benyon, Lord Lieutenant of Berkshire and chancellor of the University of Reading, a leading figure in agriculture and stock-breeding, on February 14, aged eighty-five years.

Prof. Bohuslav Brauner, lately professor of chemistry in the Charles' University, Prague, sometime Berkeley fellow of Owens College, Manchester, on February 15, aged eighty years.

News and Views

Robert Hooke's Diary

THE tercentenary of the birth of Robert Hooke, Gresham professor of astronomy, surveyor to the City of London and curator of experiments to the Royal Society, occurs on July 18 of this year. Hooke appears to have kept a continuous diary for the greater part of his life, and parts of his daily journal have been found in three different libraries. The importance of the first part was realised by Dr. Jean Pelseneer of Brussels, who directed the attention of the Royal Society to its existence in 1928, with the permission of the authorities of the Guildhall Library, Mr. H. W. Robinson made extracts, some of which were published by Dr. Pelseneer in *Isis* (February 1931). Afterwards, Mr. Robinson discovered another and later part of the diary in the British Museum, where for more than a hundred and sixty years it had been catalogued as the diary of James Petiver. The Guildhall portion of Hooke's diary is the most important, and is full of interest from all points of view. It records meetings of the Royal Society of which no minutes occur, elections of which there are no official records extant, details of his work as architect, surveyor and contractor, his daily visits to the coffee-houses and taverns, where he joined in the discourses and gossip of the city men, details of his private life, his income, his purchase of books and necessaries of life.

BY the courtesy of the Library Committee of the Guildhall, the part of Hooke's diary in the Guildhall Library can now be published. For many years Mr. H. W. Robinson and Mr. W. Adams have been carefully transcribing the diary, and it will be published, together with a short life of Hooke, by midsummer. The work of printing and publishing has been entrusted to Messrs. Taylor and Francis, who have undertaken to produce the book with the aid of a subsidy from the Royal Society. Of more than passing interest is the fact that the house occupied by Messrs. Taylor and Francis is supposed to have been built during the period of the diary, and most probably by Sir Christopher Wren and Robert Hooke. It may be remembered that Dr. R. T. Gunther has already published three volumes of Hooke's works in his series of books on "Early Science in Oxford".

Tribal Justice in Australia

A PERTINENT example of the practical bearing of the results of anthropological investigation is afforded by the defence set up in a trial for murder of two aborigines from Alice Springs, South Australia. The facts of the case are set out in a dispatch from the Adelaide correspondent of *The Times* in the issue of February 15. The defence rested on a plea of tribal justice. It has been put forward that the two accused were acting in accordance with custom and under the instructions of the elders of the tribe in putting to death a man who had revealed ceremonial secrets to a woman. Failure to comply, it was stated, would have entailed death. As might be expected, anthropologists have not failed in the endeavour to bring the aboriginal point of view before the court. Expert witnesses, however, were not heard, but their special knowledge was placed at the service of the defence. Ever since Spencer and Gillen first recorded, nearly forty years ago, the special reverence of the natives of Alice Springs for everything pertaining to tribal ceremonial, anthropologists would have been prepared to expect death as the logical consequence of so grave a threat to tribal safety as the breaking of taboo involved in the disclosure of ceremonial objects or procedure to a woman. It is, at the very least, the equivalent of a combination of high treason and sacrilege in a civilised community. As recent trials in Africa have shown, a court rooted in European law is not prepared to admit that in such cases tribal justice may demand and exact the supreme penalty, in the manner in which in a civilised society a traitor who discloses State secrets may be imprisoned for life or condemned to death. Those who carry out the sentence of the tribe must, in accordance with the laws of the country, be adjudged guilty of murder, even though the extreme penalty may not eventually be imposed.

Organisation of Agriculture in Australia

DIFFICULT circumstances in the agricultural industries of Australia are giving rise to much-needed co-operation between Commonwealth and States. In December last a conference of ministers at Canberra determined to establish an Australian Agricultural Council, to provide for continuous consultation among the Governments on economic aspects of agriculture, the members to be the Federal Minister for Commerce, the Minister in Charge of Development and Scientific Research and the State ministers concerned. This body will be supported by a permanent technical committee which is identical in personnel with the former Standing Committee on Agriculture of the Council for Scientific and Industrial Research, but which will now have greatly increased responsibilities. Its members are the six permanent heads of the State Departments of Agriculture, the three executive members of the Council for Scientific and Industrial Research, the Secretary of the Department of Commerce and the Director General of Health. Besides its duties on the side of agricultural economics, this committee is charged with (i) securing co-operation and co-ordination in agricultural research throughout the Commonwealth; (ii) advising Commonwealth and State Governments, directly or through the new Council, on matters pertaining to the initiation and development of research on agricultural problems; and (iii) securing co-operation between Commonwealth and States, and between the States themselves in all quarantine measures relating to pests and diseases of plants and animals, and advising Governments thereon.

Training in Food Technology

THE Food Group of the Society of Chemical Industry met on February 13, at the London School of Hygiene and Tropical Medicine, to take part in a discussion on "The Training of the Food Technologist", opened by Dr H B Cronshaw, editor of *Food Manufacture*, the *Industrial Chemist* and other publications As Dr Cronshaw's paper had been circulated before the meeting, he gave a brief summary of the more contentious parts and showed a number of slides illustrating numerous institutions, chiefly in North America, at which research and teaching in food technology are combined to various degrees The main part of Dr Cronshaw's paper, however, and that which gave rise to most discussion, contained a plea for the introduction in Great Britain of special post-graduate courses in food technology at suitable universities and colleges Dr Cronshaw's paper included a comprehensive and very useful survey of the kind of problems with which the food technologist is likely to be confronted, as well as some ingenious classifications of the type of product with which these technologists have to deal For this reason alone its publication in full in *Food Manufacture* will be anticipated with much interest His main plea, however, was subject to considerable criticism by various members of the Society, particularly on the grounds that it tended to over-emphasise the need of specialised technological knowledge in the young post-graduate entering industry, and so to run the risk of supplying him inadequately with the essential scientific outlook. Some of the discussion also directed attention to the importance of considering pre-graduate as well as post-graduate studies, and even of elementary and secondary education

Museum of the History of Science at Oxford

ON February 12 Congregation at Oxford unanimously passed the statute which alters the name of the institution housing the Lewis Evans and other collections of scientific instruments to the "Museum of the History of Science, Old Ashmolean Building". The first step towards the full recognition of this institution—hitherto governed by decrees—has thus been taken The museum is to be administered by the Vice Chancellor, the Proctors and six others, three of whom will be appointed by the science boards. At the moment there will be no extension of the premises. A decree, however, was also passed assigning the main ground-floor room of the Old Ashmolean to the museum at a date not later than 1942. This room, where in the past the New Oxford Dictionary was compiled, and the present upper-floor room, where the collections now are, should be adequate for the museum for many years. It is a pity, however, that this increased accommodation, at the moment badly wanted, cannot be definitely secured earlier, and that the University cannot promise adequate financial support for the staff in charge. It is to be hoped that such help will soon be forthcoming, so that the museum may take a bigger part in the science teaching in Oxford—an opportunity for a generous donor Congregation expressed themselves very appreciative of the work of Dr R. T Gunther, the curator, who not only created the museum single-handed more than ten years ago, but also has since given his services as administrator and teacher for a purely nominal salary

Pollution at Sea by Discharge of Oil

IN July last, the British Government, stating that representations had been made to it that the pollution of the coasts of the British Isles by the discharge of oil and oily matter outside the territorial limits by ships was increasing, suggested that the matter be referred for preliminary examination to the Communications and Transit Organisation of the League of Nations, with the view of concluding if possible an international convention At the last Assembly, this view was further explained by the British representative and it was decided that an initial inquiry should be undertaken Experts from Denmark, France, Italy, Japan, the United States and Great Britain were invited to Geneva by the chairman of the Advisory and Technical Committee on Communications and Transit These experts agreed that oil pollution caused the destruction of sea-birds, the wings of which become saturated with oil so that they cannot swim, fly or dive; of fish, particularly shellfish, and of the marine grasses which form the staple food of fish and sea-birds. The pollution of sea-beaches by oil results in harm to bathers and depreciation in value of seaside resorts, and constitutes a menace to public health, finally, the accumulation of oil drifting into harbours offers a serious risk of fire. These evils exist to a varying extent in many countries and the object in view is to provide, by international agreement, some means whereby oil-burning and oil-carrying ships may be prevented from polluting, through the discharge of oil and oily mixtures on the high seas, the coasts to which the matter is liable to drift. Some causes of pollution such as collision, or the pouring of oil on to the sea during storm to assist vessels in distress, cannot be prevented, but it is possible by co-operation to guard against voluntary discharge outside territorial limits, and the Committee of Experts recommend that an appropriate international convention should be concluded.

Security of Tenure and Intensive Farming

THE private bill promoted by the Metropolitan Water Board, which may involve the destruction of Holly Lodge Farm (see NATURE of February 2, p. 177), was read a second time in the House of Commons on February 18. Sir A. Boyd-Carpenter moved that an instruction be given to the committee which is to consider the bill to leave out works on this site, on account of the unique value of the farm as a research centre. After discussion, Sir Hilton Young, Minister of Health, pointed out that he had consulted the Minister of Agriculture on the matter and it was agreed that the appropriate means of dealing with the question was to refer it to a committee of the House. Sir A. Boyd-Carpenter's motion was then by leave withdrawn. In a letter in *The Times* of

February 15, Sir William Prescott, chairman of the Metropolitan Water Board, stated that the "site for the proposed reservoir at Walton has been selected after the most exhaustive examination of other available lands" It is not stated whether the expert opinion available to the Ministry of Agriculture or to the Geological Survey has been sought, but it is much to be hoped that such scientific advice may be consulted before the matter comes under discussion in committee of the House of Commons

A New American Balloon Ascent into the Stratosphere

FOLLOWING on the American ascent into the stratosphere last year recorded in NATURE of July 28, p 132 and November 3, p 707, 1934, careful inquiry has now shown that the mishap was caused by internal adhesions of the lower part of the balloon fabric Plans for a new ascent are well advanced The personnel of the advisory committee has been chosen by the National Geographic Society working in co-operation with the United States Army Air Corps, and once again Capts A W Stevens and O A Anderson will ascend It is gathered from the announcement by the president of the Society in the *National Geographic Magazine* of February 1935 that the arrangements will differ but little from those of last year's flight. The balloon will have the same capacity and the ascent will be made from the same place. No details are as yet available of the instruments that will be carried, but as the lifting power will be about six tons and as "special emphasis is to be placed on data that can be obtained from manned balloons capable of lifting standard laboratory instruments", there is no doubt that every possible self-registering device that might supply information about the upper atmosphere and cosmic rays will be included An advisory committee under the chairmanship of Dr Lyman J Briggs, director of the U S. Bureau of Standards, is to be congratulated on the thoroughness of its investigations of the previous failure The findings will be of greatest value to those who undertake future hazards.

A New Diphtheria Prophylactic

OWING to the prevalence of diphtheria during the last year, a considerable demand has followed for immunising agents for preventive inoculation, which is now extensively practised with good results. Various agents have been employed for this purpose, such as toxin-antitoxin mixtures and preparations of modified diphtheria toxin known as 'toxoid' An alum-precipitated toxoid (A P T) of high immunising efficiency is now available, and is issued by Messrs Burroughs Wellcome and Co , in germ-proof containers of 1 c c. and 5 c c. This substance was first prepared in the Wellcome Physiological Research Laboratories in 1926 The results of animal tests showed that it possessed considerable immunising power against diphtheritic infection, and since that date its high immunising efficiency in human beings has been established Caution has been exercised in applying the inoculation of A P T. in human beings on account of the production of a tissue response at the site of injection. This, though medically trivial, may disturb parents of inoculated children The efficiency of A P T probably depends upon the deposition of the relatively insoluble aluminium-toxoid compound at the site of injection, and from this the immunising toxoid is gradually liberated The complex toxoid compound, however, excites a tissue response in the form of a small painless nodule, and this tissue response is probably an essential factor in the potent immunisation that ensues Unpublished experiments made in the Wellcome Research Laboratories have shown that in animals two spaced injections of one tenth, or less, of the ordinary human dose results in a more rapid, or a higher, immunity than one single larger dose It is possible that a similar method may prove useful in human immunisation, the chance of troublesome local reaction being lessened by this course

Juan Fernandez and Easter Island

BY a recent decree of the Chilean Minister of Lands and Colonisation, it is reported by a correspondent of *The Times* in the issue of February 14, Juan Fernandez and Easter Island have been declared national parks This gives effect, so far as Juan Fernandez is concerned, to a proposal which was first put forward so long ago as 1921 The two volcanic islands grouped together under the name Juan Fernandez and situated four and five hundred miles respectively west of Valparaiso are of popular interest because it was on one of them that Alexander Selkirk was marooned from 1704 until 1709 , and his adventure is supposed to have inspired Defoe in writing "Robinson Crusoe" Easter Island, on the other hand, which lies about 2,300 miles from the mainland, is one of the most interesting islands of the Pacific Its archæological remains present a problem for ethnologists which hitherto has defied satisfactory solution These remains consist of more than five hundred human figures, portrait statues, carved in stone, some of gigantic size and one at least approaching forty feet in height, over two hundred stone platforms and stone houses, unique in the Pacific, relics of a race of which the present inhabitants have no knowledge Even more interesting in certain respects are the tablets inscribed in a script which no one has yet succeeded in deciphering Since 1888 the island, which has an area of about 48 square miles, has been in the possession of Chile, and has served as a penal settlement The native inhabitants, who are Polynesians with a Melanesian strain, barely exceed 200 in number, though in 1860 they numbered 3,000 , but in the 'seventies a considerable proportion migrated or was removed to Tahiti and the Gambier archipelago The decree of the Chilean Government, in so far as it will ensure the protection from vandalism of these unique relics of an otherwise unknown culture and an apparently vanished race, is a public spirited act worthy of the highest commendation

A Tidal Power Project in the Bay of Fundy

THE Bay of Fundy is well known throughout the world for the height of its tides It is not surprising, therefore, that Americans are interested in the

project for getting tidal power at Passamaquoddy Bay, which lies between New Brunswick, Canada, and Maine, U S A A full description of the project is given by H E. M Kensit in *World Power* of February The projected power house is situated entirely in the State of Maine, but as the project is an international one, the power produced would be equally divided between the two countries If we compare the estimated cost of the new project with that of the corresponding tidal power schemes in England (the Severn) and in the Argentine (San José) it comes out decidedly cheaper In the English scheme, the cost of a horse power is £31 4, in the Argentine it is £25 3 and at Passamaquoddy it is £18·9, and each is roughly of the same size The normal spring tides at the head of the Bay of Fundy range between 47 ft and 52 ft The maximum recorded tide occurred in 1869 and was nearly 57 ft At the site of the new power station, the tides will lie between 17 ft and 19·5 ft In 1930, President Hoover induced Congress to defray half the cost of a joint investigation with Canada into the effect of such a station on fisheries In this connexion, it is of interest to know that the committee on the Severn project decided that a large number of sluices open for many hours every day would obviate any detriment to fishing interests It is probable therefore that the joint commission on fisheries may present a favourable report The United States engineers indicate that there is no insuperable difficulty with regard to shipping interests, and many are hoping that this great enterprise will be carried out by private interests and capital

Habits and Evolution

At the annual conference of the School Nature Study Union, held in January, Prof. E W MacBride was the speaker, and his address upon "The All-importance of the Study of Habits for the Knowledge of Evolution" was, in effect, a statement of his evolutionary faith (*School Nature Study*, 1935, p 2). He led to his own viewpoint by a vigorous onslaught upon the faiths of others. Evolution we all accept, but the way thereof is dark Darwin, we learn, with his natural selection of variations, was a false prophet, for natural selection does not work even if small deviations were heritable, which they are not The mutationists are equally in error, for a mutation is a suddenly produced disturbance of development which persists only so long as the conditions producing it continue According to Prof MacBride, the truth lies with the neo-Lamarckians in their belief that use and disuse, in short habit, have been the mainspring of the progress of evolution "Habit long persisted in does affect posterity and is the driving force in evolution , the personality, if we may use such a word, of a living being, is made up of a complex of inherited habits, and habits deeply ingrained are extraordinarily persistent." Prof MacBride supports his thesis and trounces his opponents by quoting experimental results well selected for his purpose. Thirty years ago no biologist would have listened to the Lamarckian view ; nowadays we are not so sure.

Scheme for Eradication of Cattle Tuberculosis

The Ministry of Agriculture and Fisheries has issued a document describing 'arrangements' made by the Ministry under Section 9 of the Milk Act, 1934, for promoting the establishment of cattle herds officially certified to be free from tuberculosis Any owner who has taken steps to eradicate the disease from his herd, and is a 'registered producer' under the Milk Marketing Scheme, is entitled to apply to the Ministry for an official test of his herd, providing no reactors were found in the herd at the last two tests made under certain conditions on the owner's behalf. If the owner satisfies the Ministry as to the management and conditions of herd and farm, and agrees to observe the regulations, an official tuberculin test of the herd will be made by the Ministry free of charge, and provided no reactors are found, the herd will be placed upon a 'register of attested herds'. The scheme, which is a voluntary one, came into operation on February 1, and owners who desire to avail themselves of it should communicate with the Secretary, Ministry of Agriculture and Fisheries, Whitehall Place, London, S W 1 One advantage of attestation is that the owner will be entitled to a bonus of 1*d* per gallon for all milk sold under the marketing scheme of the Milk Marketing Board

Iodine and the Thyroid Gland

In the twenty-ninth Bedson Lecture delivered on February 8 in Newcastle, Prof C R Harington dealt with the relation of the thyroid gland to iodine He traced in detail the parallel histories of the anatomy, physiology and pathology of the gland, culminating in the work of Kocher, the treatment with sheep gland extracts by Murray, and the iodine treatment by Coindet of goitre and cretinism Although the 3 5-diiodotyrosine also present in the 'colloid' must take part in the activity, as this is proportional not to total thyroxine but to total iodine, the two dipeptides made from them have not proved to show the full activity, so that possibly they are linked to, or by, other amino acids, it being fairly established that no other compound of iodine is present The general picture, then, is as follows. Iodine is readily taken up by the gland with formation of 3 · 5-di-iodotyrosine, which is elaborated into the globuline , this is the storage form, the so-called 'colloid', of the epithelial layer. When total iodine in the gland falls below 0·1 per cent, the colloid is soon exhausted and the epithelium extends to form goitre Later, generally in pre-natal conditions, atrophy occurs leading to cretinism. Restoration of iodine at the former stage leads to distension by colloid, and the epithelium reabsorbs. In the normal state the tyrosine derivative is partly converted into thyroxine, and these two substances form the hormone which regulates bodily metabolism in general. In support of this view, it has been shown by Prof. Harington that the tyrosine and thyroxine are of the same stereochemical configuration by the preparation from each of thyronine (desiodothyroxin).

Ideal Home Exhibition

THE nineteenth *Daily Mail* Ideal Home Exhibition will open at Olympia, London, on March 26. A feature of the Grand Hall will be the great murals, 36 ft. high and 374 ft. long, from end to end of each side of the hall. The eighteen panels will bring to the eye, not only the vivid story of the changing world but also the actual features of more than a thousand men and women—pioneers, social workers, explorers, scientific workers, engineers, industrialists and others who have achieved distinction in helping to change the world for the better. This work has been carried out to the original designs of Oswald Cunningham. Among the features of the Exhibition will be a £50,000 installation of the very latest types of British-made canning machinery, weighing nearly 40 tons, to demonstrate the rapid strides made by this new home industry. Twenty-five years of progress in things engineering and scientific will be found on the second floor of the Empire Hall—the development of electric lighting, telephones, aviation, travel, transport, sound-recording, reproduction and radio. The General Post Office will have in operation the latest of the many wonderful machines utilised in modern communications. The strides made by 'staybrite' steel, which made its debut at the exhibition last year, will be demonstrated, and there will be numerous exhibits of beauty and utility for the home for furnishing, lighting, heating, decoration, labour-saving and recreation.

Improving Long-Distance Telephone Transmission

THE rapid improvement of the technique of radio communication during the last ten years is now having a beneficial influence in the development of long-distance telephone transmission. In particular, the improvements made in vacuum valves due to the demands made by broadcasting engineers have led directly to great improvements in the design of the repeater valves used in long-distance telephony. It is well known that during conversation over long lines by means of carrier frequency equipment the sounds heard sometimes vary greatly in loudness. This is attributed to the fact that the attenuation of the line, especially when overhead wires are used, changes with climatic conditions, temperature, etc. With cable circuits, the loudness remains much more constant. The phenomenon is analogous to the well-known phenomenon of 'fading' in radio transmission. Successful attempts have recently been made to mitigate this trouble. A paper by H. Sterky and R. Stalemark which appears in *Ericsson Technics*, No. 3, 1934, describes an automatic method of compensating for these variations which has been used in practice for the last two years with good results. The development of the method is due to the telephone firm of Ericsson, Stockholm. It depends on the well-known mathematical theorem that a carrier wave modulated by a wave of voice frequency is equivalent to three separate simultaneous oscillations. One of these has the frequency of the carrier wave; the others, called side-band waves, are of higher and lower frequency respectively. In the Ericsson device, during conversation, the carrier and one side-band wave are transmitted. Signalling is done by modulating the carrying wave with the 'ringing' current. It is stated that the volume control of the sound obtained in this way is very good.

Shellfish and the Public Health

THE Minister of Health has issued an Order, Public Health (Shell-fish) Regulations, 1934, revoking previous regulations, and regulating the sale of shellfish for human consumption, which came into operation on January 1. The new regulations give powers to local authorities to investigate suspected layings, to prohibit the sale of shellfish from polluted layings, and to provide cleansing apparatus if considered necessary. (Statutory Rules and Orders, 1934, No. 1342. 2*d*. Circular 1446. 1*d*. H.M. Stationery Office.)

International Office for the Protection of Nature

THE Belgian Government has by Royal decree officially recognised the International Office for the Protection of Nature, Rue Montoyer 21, Brussels, and has appointed the following delegates to be its representatives on the General Council of the Office: Delegates for Belgium, Baron E. de Cartier de Marchienne, Belgian Ambassador in London, and Count Henry Carton de Wiart, former Prime Minister; Delegates for the Belgian Congo and the Mandated Territory of Ruanda Urundi, P. Charles, Minister of Colonies, and Prof. V. Van Straelen, director of the Royal Belgian Museum of Natural History and president of the Institute for National Parks in the Belgian Congo.

Oxidation-Reduction Potentials in Bacteriology

THE fact that a second edition of Dr. L. F. Hewitt's monograph on "Oxidation-Reduction Potentials" has been found necessary indicates the interest taken by biologists in the subject ("Oxidation-Reduction Potentials in Bacteriology and Biochemistry". published by the London County Council. Pp. 81. 2*s*.). Since the first edition was noticed in our columns (NATURE, **128**, 73; 1931) the subject has advanced steadily, and the author has taken the opportunity to revise and extend the text and bring the bibliography up to date. The study of electrode potentials is proving of assistance in the practical question of the rationalisation of culture media and cultural conditions and is throwing light upon the biological behaviour of organisms, such as the maintenance or loss of virulence, questions of great importance in medical practice.

Improvement of Grassland

As much as eighteen million acres in England and Wales consists of grassland, and considerable attention has been paid in recent years to its improvement. The need for authoritative information on this important subject led to the publication of Bulletin No. 3, "The Improvement of Grassland", by the Ministry of Agriculture and Fisheries, a fourth and revised edition of which has been issued (1*s*. net). The revision of the text has largely been carried out by Prof. J. A. Hanley (Armstrong College, Newcastle-

upon-Tyne) who has taken the opportunity of incorporating in the present issue the deductions drawn from the work done under the Ministry's 'Grassland Campaign', and also to include a section on the comparatively new system of rotational or 'managed' grazing The sections on the renovation of worn-out grassland and seed-sowing remain substantially as written by Prof. R G Stapledon, of the Plant Breeding Station, Aberystwyth

Medical Research in South Africa

THE annual report by the director, Sir Spencer Lister, of the South African Institute for Medical Research, Johannesburg, gives an account of the routine and research work of the Institute for the year 1933 Concentrated anti plague serum, prepared in the Serum Department, has been tested experimentally, and has been found to have four times the protective and curative power of the unconcentrated serum, concentration being in the same ratio Considerable difficulty has been experienced in maintaining the virulence of the plague bacillus in culture, and this difficulty has not yet been overcome The study of pneumonia as it occurs among native miners of the Witwatersrand goldfields was continued, and the work confirms previous findings that the disease is not a pure pneumococcus pneumonia of the earlier days of the Rand, but that other organisms are associated with, or replace, the pneumococcus, namely, the streptococcus, staphylococcus and influenza bacillus During the year, a case of human rabies due to a cat bite was observed; the incidence of human rabies infection is on the increase in South Africa, being conveyed by the cat, the tame meercat, and occasionally the dog The observations upon dust estimation and control in the mines have been extended, and research upon several other subjects has been continued

Astronomical Phenomena in March

MERCURY is now a morning object, and attains its greatest elongation of 28° W on March 15 Venus, on the other hand, is moving round to its greatest eastern elongation (45° E. on June 30) and has already become a conspicuous object in the evening sky just after sunset Mars is well placed for observation, being very nearly in opposition Jupiter is a morning object, and Saturn is very near the sun An interesting conjunction of Venus and Uranus will occur on March 22 at 7 hours, when the planets will only be separated by 0 4° This conjunction will, of course, be invisible in England, but the two planets should be seen close together, in a small telescope, on the evening of March 21 or of March 22 Neptune is well placed for telescopic observation, being in opposition to the sun on March 4.

Announcements

PROF W. J. DE HAAS, University of Leyden, informs us by cable that on February 15 he succeeded in reaching a temperature only five thousandths (0·005) of a degree above absolute zero. Particulars of this remarkable achievement will be awaited with great interest

AT the annual meeting of the Royal Society for the Protection of Birds to be held at the Westminster Palace Rooms, 44 Victoria Street, S W 1, on Friday, March 1, Her Grace the Duchess of Portland, president of the Society, in the chair, a motion will be submitted "That the Governments of all maritime nations be urged to give the strongest possible support to the League of Nations in their endeavours to secure the universal adoption of effective measures for preventing the pollution of the seas by oil"

IT is proposed to hold an exhibition of English periodicals and reviews in the library of the University of Coimbra, Portugal, early this year It is hoped later to transfer the exhibition to Lisbon, Oporto and Braga It appears that English is the second foreign language in Portugal, and a large proportion of its inhabitants have a working knowledge of the language; but there is a general ignorance of what periodicals and reviews are published in English. It is hoped that the exhibition will remedy this state of affairs Further information can be obtained from the Director, Biblioteca da Universidade, Coimbra, Portugal

REFERRING to Mr C R Cosens's letter in NATURE of January 12 (p 71) on "Designation of Logarithms to Base e", Dr J Satterly, of the University of Toronto, writes "Long ago I decided that logh was too long and $\log_{10}$ and $\log_e$ awkward and have recently designated for blackboard work common logarithms and natural logarithms as 'ln' and 'le', pronounced something like 'Ellen' and 'Elsie' respectively."

A BOOKLET dealing with the chloramine group of antiseptics has been issued by Boots Pure Drug Co, Ltd, Station Street, Nottingham, from whom it may be obtained free of charge. Attention is directed to the use of 'chloramine-T' and 'dichloramine-T' in the treatment of infected wounds, and to 'halazone', a most satisfactory chlorine compound for the sterilisation of drinking water

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A computer (class II) to the Ordnance Committee, Royal Arsenal, Woolwich, S E.18—The Secretary (Feb 25) A lecturer in electrical engineering at Chesterfield Technical College—The Director of Education, County Education Office, St Mary's Gate, Derby (Feb. 25). A University lecturer and a part time University lecturer in the Faculty of Mathematics, University of Cambridge—The Secretary to the Faculty Board of Mathematics, St John's College, Cambridge (March 2). Junior scientific officers in the Aerodynamics and Radio Departments of the National Physical Laboratory, Teddington—The Director (March 4). A resident lecturer (chemistry or physics) at Girton College, Cambridge (March 6) An assistant lecturer in zoology in the University of Bristol—The Secretary (March 11). A Henry George Plimmer fellowship in pathology at the Imperial College of Science and Technology, Prince Consort Road, London, S.W 7—The Rector (June 17).

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 310

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Deep Diathermic Effect and Localisation by Means of 'Auxiliary Dielectric Electrodes' in the Condenser Field

AT present it is impossible to heat the deeper parts of a body of uniform transverse section and homogeneous structure to a higher temperature than its peripheral parts by means of high-frequency currents With present-day methods the loss of oscillating energy by leakage and radiation is so great that probably less than 20 per cent of it is used for heating effects Further, it is impossible to localise, to concentrate or even to direct the field more than very vaguely. Any object brought into the field deforms it in an uncontrollable way

I have found a method by which the condenser field can be made to produce a greater effect at the deeper parts than at the peripheral parts by the use of 'auxiliary dielectric electrodes' Between the two metal plates, of 2–3 in diameter, of the high-frequency apparatus is placed a glass tube, about 4 in. long and half an inch in diameter Near one end is a side tube for filling The ends are closed by flat glass walls An air space of ½ in is interposed between the metal electrodes and the glass ends The tube is filled with white of egg On exposure to the field, coagulation commences at the middle of the tube and gradually extends towards the ends, which remain cool. The coagulation does not occur if the long axis of the tube is parallel to the electrodes If in this position suitable cylindrical auxiliary dielectric electrodes, one to two inches in diameter, made of agar, wax, ebonite, etc , be placed so as to occupy the space between the metal electrodes and the tube and be in contact with electrodes and tube, then coagulation occurs in that part of the tube which lies between the auxiliary electrodes If we arrange the tube again lengthwise and apply a short dielectric cylinder to one end, a longer one to the other, the point of coagulation will be moved towards the longer dielectric. Different shape or different material of one dielectric may modify this effect

A similar experiment can be performed with minced muscle, liver, kidney, etc In some experiments it was possible to heat a 580 gm piece of ox-liver to a considerably higher temperature in the centre than at the borders For example, thermometers 0·6 in. from each side, and a thermometer in the middle and so 2·5 in from the sides, registered as follows :

	Left edge	Centre	Right edge
Starting temperature	12°	9°	11°
After 10 minutes	15·8°	15·6°	15°

At this time the temperatures throughout the piece might be considered as equal. The room temperature was 18·5°. The following temperatures were reached :

After 10 minutes	19·6°	23·3°	18·3°
After a total of 60 minutes	31·7°	40·7°	31·2°
Total rise	19·7°	31·7°	20·2°

Of course, in the living animal such differences will scarcely be obtainable, except in quite special circumstances, on account of the considerable heat convection by the circulating blood and lymph The effect is nearly the same for any wave-length between 3 and 30 metres

These experiments prove the possibility of deep-heating, of localising and of concentrating the lines of force and of directing the field A further advantage is the considerable reduction of the losses by leakage and radiation , the loss in the dielectric itself depends on its transparency for these waves

Differences in the size of cross sections of different parts of the object cause an increased heating effect on the site of the smallest sections, and prominent points or corners sometimes heat up quickly This inconvenience can be overcome by moulding the dielectric substance around or partly around the smaller cross sections, so that they are artificially increased. In that way it is possible to heat equally through a cross-section situated anywhere by leaving this section free and moulding dielectric substance round the other parts of the object This produces a localised heating of the whole section, for example, an elbow or a knee

The greatest difficulty in human application is the apparent necessity of electrodes of bigger size than the object Not only is the relation of the size of the electrodes to the object important, but also the relation between the length of the object to its cross-sections This can be corrected to a great extent by suitably shaped auxiliary electrodes Recent experiments seem to show that it is sufficient if one electrode only is bigger , and if one does not wish to reach a higher temperature in the centre than near the surface, then two small electrodes are sufficient for a practically equal heating

Well Gauges as Seismographs

A NUMBER of workers[1] have noted that distant earthquakes are registered on automatic water stage recorders operated on deep wells In each of these cases, the time scale was so small that the earthquake record was merely a thick line transverse to the direction of time movement We recently fixed a gauge in a well at Lodi, California, with a Bosch-Omori seismograph drum, rate 15 mm /min , and smoked paper recording The well is known as 3612A2. It is located at lat 38° 07′ 38″ N , long 121° 16′ 29″ W. in the Mokelumne area of the San Joaquin Valley. It is of circular cross section, diameter 6 in , depth 76·0 ft. below ground surface which is at an altitude of 46·9 ft above mean sea-level. This well, which is not cased below the water surface, is in unconsolidated alluvial deposits of

Pleistocene and Pliocene age. It presumably penetrates to a confined aquifer or aquifers No log is available. The gauge is composed of a copper float, $4\frac{1}{2}$ in in diameter, which operates a stationary 8 in. float-wheel by means of a cord and counterweight A 4-in diameter axle mounted on the float-wheel shaft is connected at its upper periphery by a copper ribbon to an auxiliary wheel in the same plane and at the same elevation, on the other side of the recording drum, tension in the ribbon being maintained by a second counterweight below the auxiliary wheel. An aluminium stylus attached to the copper ribbon thus moves horizontally a distance equal to one half that which the float moves vertically This stylus records on smoked paper on the drum. The minutes are marked on the record by means of a pendulum contact-making clock (supplied by Spindler and Hoyer with Bosch-Omori seismographs), actuating a relay circuit coupled to a solenoid, which energises the magnetic counterweight. Thus the stylus is displaced each minute. The clock correction is obtained daily.

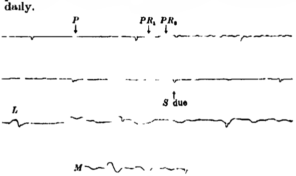

FIG 1

On November 30, 1934, at about 2^h 05^m 12^s, G.M T , an earthquake occurred with epicentre at 18 5° N , 105° W , as placed by the Jesuit Seismological Association This was the first shock to be well recorded on the Lodi well gauge. The record is reproduced in Fig 1 The epicentral distance of Lodi was about 25°. The P phases were all recorded, the reflections PR_1 and PR_2 particularly well The S waves were not distinguishable At the Berkeley station (epicentral distance 25°) the Bosch-Omori seismographs (static magnification 40) wrote an excellent record of this shock The amplitudes of the S waves were about four times those of the P waves. Some workers have hesitated to say definitely that the second preliminary or S wave is a shear wave. It appears that its failure to record on the well-gauge establishes definitely that it is an equivoluminal wave, since it is to be expected that only waves involving change in volume, and hence hydrostatic pressure, will affect the water-level More sensitive recording apparatus may eventually reveal some small motion when S is expected due to the surface reflection of some of the S energy as P waves

The surface waves are well marked on the record. These begin with the wave tabulated as L by Macelwane in his table It has been clear for some time that this wave is not a Love wave since it has usually a vertical component. The recording of it on a device not sensitive to shear waves confirms this. The Love wave is regularly recognised on seismograms much earlier and is now frequently called G. It appears possible to recognise a later group of waves resembling the M waves on many seismograms Although not usually tabulated, there are three groups of seismic surface waves : G (Love waves), L and M Only the latter two were recognised on the well record.

The appended table gives the observed and computed times of the various groups of waves The maximum half amplitude on the record was 0 8 mm

Phase	Observed Time			Computed Time		
P	2^h	10^m	36^s	2^h	10^m	37^s
PR_1		11	16		11	10
PR_2			28			23
L		17	02		17 4	
M		20	21		19 8

Sedimentation Equilibrium Measurements with Low Molecular Substances in the Ultra-Centrifuge

IN a recent paper[1] I have shown that it is possible to study the sedimentation equilibrium of the heavier inorganic salts (for example, CsCl, CsI, KIO_3, $LiIO_3$, $HgCl_2$ and others in 0·1 molar solutions) in the ultra-centrifuge of The Svedberg[2]. These experiments were carried out in a centrifugal field of about 200,000 times gravity By means of a refractometric method worked out by O Lamm[3] it was possible to study the change in concentration in the cell From the variation of the concentration set up by these intense centrifugal fields with the distance from the axis of rotation, the molecular weight of the substance may be calculated when the speed of the centrifuge and the temperature of the cell are known In addition, it is necessary to know the density of the solution and the partial specific volume and activity coefficient of the substance in solutions of like concentrations

The calculated molecular weights agreed fairly well with the known values for these substances except in the cases of the substance with the lowest molecular weight, CsCl, where the difference in concentration was very small

Quite recently, Prof Svedberg has greatly improved his ultra-centrifuge (see Svedberg, *loc cit*), and in October last a new rotor of a somewhat different construction from that already described in NATURE was tested at 155,000 r.p.m. and was ready for general work up to a speed of 140,000 r p m , corresponding to a centrifugal field of 710,000 times gravity in the middle of the cell. Although the cell for this rotor was not especially constructed for equilibrium experiments, it was decided to try to use it in this way with low molecular substances, at a speed of 120,000 r.p m., corresponding to a centrifugal field of 525,000 times gravity. At once it became clear that the difficulties in such high fields were very much larger, because the cell was deformed continuously. However, it was possible to diminish

the influence of this deformation on the measurements by making alternate experiments with pure water (for the reference scale, for details see Pedersen, *loc. cit.*) and the salt solution In this manner we are able to relate values for a certain run to the run immediately before and immediately after it (each run took 6–8 hours)

By using this procedure there could be measured the change in concentration in the cell for such low molecular weight substances as NaCl, LiCl and the simplest amino acid (glycocoll) The molecular weights found were for NaCl 57 4 (58·454), for LiCl 37·8 (42·397) and for glycocoll 68 1 (75 05) The values in parenthesis give the true molecular weights. This result means that it is actually possible by means of the ultra-centrifuge to determine the molecular weight of all substances (soluble to a certain extent in water) from LiCl up to the huge hæmocyanine molecules (molecular weight 6,000,000)

The experimental difficulties connected with the gradual deformation of the cell we hope to be able to overcome by introducing certain alterations in its construction.

The calculations of these experiments were carried out in a somewhat different way from that used before[1], introducing the refractive index increment of the substance. Assuming that the same total amount of substance is present in solution in the cell when the equilibrium is established as at the start, it is possible by means of an integration method to determine the concentration of the substance at any point of the cell, and after this the molecular weight may be calculated either in the usual way or by introducing the value found for dc/dx in the differential formula for the molecular weight

Details will be published elsewhere

Use of the Centrifuge in Determining the Density of Small Crystals

IN a previous letter[1] we described a method of determining the density of small crystals of a substance with the centrifuge for the purpose of determining its molecular weight. It has since been brought to our notice that essentially the same method has been used by S. B. Hendricks[2] though with a different object We should, therefore, like to correct the impression that we claim any novelty for this method of density-determination, while still wishing to point out its usefulness as a method of determining molecular weights to a high degree of accuracy

Mechanism of Respiration

THE respiration of the minced breast muscle of the pigeon has been studied by means of specific poisons (malonic, maleic and arsenious acid) Experiments show that in the main process of respiration, no substances other than succinic acid and its first oxidation product, fumaric acid and the hydrate of the latter, malic acid, are oxidised directly by the Warburg-Keilin 'Atmungsferment-Cytochrom' system Both succinic and malic acids are activated by the corresponding specific dehydrogenase Only these two dehydrogenases seem to be connected immediately with the Warburg-Keilin system Succinic acid is oxidised by them to fumaric, malic to hydroxy-fumaric acid Both oxidations are reversible

Foodstuffs are oxidised by dismutating them with oxidation products of succinic acid, which products thereby become re-reduced and act thus as catalytic hydrogen carriers The 'oxidation system' is an enzyme complex acting specifically on succinic acid and its oxidation products Fermentation is an intramolecular dismutation Oxidation is dismutation with oxidised succinic acid

Cosmical Chemistry

MANY will read with interest and admiration Prof H N Russell's fascinating and masterly address published as a supplement to NATURE of February 9; it is all that an address should be on such an occasion Having watched the story of ultramundane chemistry unfold from all but its Bunsen and Kirchoff-Stokes beginning, especially during the turbulent Lockyer period, I perhaps can appreciate both its beauty and the greatness of our advance in knowledge more than most, so may be allowed to tender to Prof Russell the thanks that so many, I am sure, will wish to express

What would the founder and first editor of NATURE have said to the use made of the spectroscope since he turned his instrument to the sun and discovered helium, the only element discovered in the sun, perhaps some day, when we draw pictures of atomic structure as we now do of molecular, to be recognised as the fundamental element as benzene is the fundamental carbohydride? The wave of enthusiasm then excited has rolled on with ever increasing amplitude and certainty of direction

The cosmos stands revealed before us, in wondrous simplicity too. Even organic chemistry is lifted up to the stars and shown to have the simplest possible beginning there in methane, together with ammonia Some planets, it seems, may be worlds of Franklin chemistry, with ammonia as snow

We are in face of a transcendent geology but whilst readers of NATURE may geologise on Mars and recognise ferric red on its surface rocks, few of our schools pay the least attention to mundane geology Dust has no ethics in most eyes our women wear it but without understanding Love of colour is a barbaric trait—understanding is not Are the masses ever to remain barbarians? What is to be the use of leisure in the future? At least, we should seek to civilise our politicians and all who strive to

put themselves in authority over us: the freedom to display ignorance granted to those, as at Wavertree these last few weeks, is nothing short of a menace to society.

Still, the physicians have to heal themselves. When, fifty years ago, I began to teach my engineering students at the 'Central' to look chalk in the face, in the hope of leading them to take some slight interest in geology, I had the beautifully coloured large Geological Survey map of our islands, made by joining the separate sheets, pasted upon the wall, on the stairway leading to the laboratory, varnished and framed; it was there until I left in 1914. I made the class buy the key map of the Survey and Charles Kingsley's lectures on "Town Geology", advising students to hang the map up in their bedrooms. Looking for the map at the jubilee celebration, at the 'Central', this week, I found the wall reduced to the condition of the map bought by the 'brave Captain' in "The Hunting of the Snark"—a perfect and absolute blank! Modern professors of engineering have no use for geology; their hearts are so encased in steel that they no longer see anything in stones. A like map has reigned at the head of the stairway to the large science workshops at Christ's Hospital since the school was opened at Horsham more than thirty years ago. I expect soon to see its place taken by School Certificates. Geology is only brought before us to-day by the saving grace of the railway poster.

Wasting Disease of *Zostera marina*

IN Dr. Kathleen B. Blackburn's letter on this subject[1], the conclusion seems well established, through a study of the chromosomes, that the narrow-leaved form of the eelgrass (grass wrack), which has in many of the diseased areas replaced the larger and broader type of plant, is clearly a form of *Z. marina* and not a hybrid of *Z. marina* and *Z. nana*, as some have believed. Miss Blackburn therefore suggests that the difference in the width of the leaves of varieties of *Z. marina* may be a purely ecological character. She further remarks that, in the localities examined, the width of the leaf of *Z. marina* was directly proportional to the depth of the water, and that the very narrow-leaved forms were those that had been longest exposed by the fall of the tide, while the broader were those that had not been exposed at all.

It may be of interest to report that on the American coast the evidence does not entirely support this ecological interpretation. *Zostera marina* is the only species recognised as occurring on this side of the Atlantic, and it extends from southern Labrador (with outlying stations in southern Greenland and in James Bay) southward to a point near the city of Beaufort, North Carolina. In travelling from north to south, one notices a gradual and progressive reduction in the size of the plant and in the width of the leaf blade. Leaves from plants found in northern Maine, for example, are often more than three times the width of those from Pamlico Sound, North Carolina. The diameter of the rhizomes likewise undergoes reduction southward, and there is an accompanying reduction in the number of leaf veins.

Dr. Setchell, in his excellent paper, "Morphological and Phenological Notes on *Zostera marina* L."[2], does not specifically state that the plants in their first year of growth are smaller and have narrower leaves than in the more mature stages, although he seems to demonstrate this in his illustration of stages in the growth of plants. From observation of *Z. marina* in places where it has begun to re-establish itself along the Atlantic coast from Maine to North Carolina, there is ample evidence of this habit of growth. In many such places the plant has shown some slight evidence of recovery, and wherever examined, the new growth has been found more slender than in the mature plants.

At a point on the coast of eastern Maine where the average tide fluctuation is nearly 18 ft., I found eelgrass growing in more than 10 ft. of water at mean low tide. The plants here were narrower than in those that appeared to be of the same age growing in shallower water. It does not seem, therefore, that the depth at which the plant grows always is positively correlated with breadth of leaf.

The observed characters of *Zostera marina* on the Atlantic coast of North America would seem to indicate that robustness is correlated with both temperature and age of the plant, the northern forms of a given age being larger and having broader leaves than those from farther south. Perhaps the length of the growing season may be an important factor in this regard. Setchell shows that vegetative growth of this species takes place when the water temperature is 10°–20° C., while reproduction occurs only between the temperatures of 15° and 20° C. According to the same author, no growth or reproduction takes place when the temperature is either above or below these limits or during the period when the temperature is declining from 20° to 10° C., which he calls recrudescent rigor. Thus, there is a shorter growing season in extreme southern latitudes than in most of the northern areas of the plant's normal range.

Among local factors that frequently influence the development of submerged aquatics may be mentioned water currents, temperature, the condition of the bottom, particularly in regard to type and texture of soil, and the chemical composition of the water, especially in relation to fluctuation of salinity of tide water sections of coastal river systems. My own observations seem to show that the general vigour of *Zostera marina* is lessened in areas of greatly reduced salinity, and that at such places the leaf is comparatively narrow. The above and other factors are to be considered in any interpretation of the causes of abnormal leaf development.

It is conceivable that, in some circumstances, as in British waters, the plants might be stimulated by depth to produce broad leaves, yet this does not seem to be typical of conditions on the American coast.

Germination of Resting Spores of Onion Mildew (*Peronospora Schleideni*)

IN spite of the ubiquity of the Peronosporas and the frequent occurrence of sexually produced spores amongst the various species, very little is known in regard to the ultimate fate and method of germination of such oospores. Several workers have recently commented on this fact.

In a previous publication[1] attention was directed to the failure to germinate resting spores of *Peronospora Schleideni* in the laboratory, even when subjected to different treatments. The peculiar germination of one untreated spore, kept in a sealed moist chamber for several months, was mentioned in the same paper. Since then, the germination of a number of resting spores of this fungus has been seen under more natural conditions.

In the year 1930, I found a crop of onions in which enormous numbers of resting spores of onion mildew were being produced in the foliage. A sack-full of these leaves was collected and taken home, being then trampled into a large box provided with holes at the bottom for drainage. Bacterial action soon commenced and the leaves went down into a vile-smelling mess, which after the lapse of a few weeks dried up, leaving a fine material a couple of inches deep in the box consisting of decayed leaf tissue and abundance of resting spores. The box has remained fully exposed in a garden since then, and periodically, a little of the fine material has been removed in order to photograph any change occurring in the spores, and also to test for germination. The collapsed oogonium is remarkably persistent, and forms an additional protective layer 2–3μ in thickness around the thick spore wall.

Little or no change was seen in the spores until they were three years old, when it was found that in some cases the oogonium had disappeared wholly or in part, and the spore wall had thinned down to 2–1μ. Germination of an odd spore was obtained at the end of four years, and after a further five months, on placing some of the material from the box in water in a warm room, approximately 1 per cent of the spores germinated after eleven days, a total of twenty-seven being observed. Germination in all cases was by a stout germ-tube 6–9μ in diameter, which was capable of considerable growth in water, up to 960μ. In a number of cases this germ tube branched. Spores which were partly free from the oogonium and germinated were of a light straw colour; in some instances the germ-tube pushed its way out through the enveloping folds of the persistent oogonium. Whilst thinning of the spore wall has taken place in quite a considerable number of the spores, others show no visible change from those photographed at the end of the first year, and judging from their appearance they are probably good for another five years.

So far as I am aware, the above is the only record of the germination of resting spores of onion mildew.

Crystallisation of Human Serum Albumin

APART from Oswald's report[1] that he had obtained globuliths from the albumin fraction of human ascitic fluid, we have been unable to find any account of the crystallisation of human serum albumin. Recently we have succeeded in obtaining albumin crystals from two separate batches of pooled human sera.

Serum was separated from the clot, heated for 25 minutes at 56° C. and fractionated within two or three days of bleeding. After addition of an equal volume of saturated ammonium sulphate and removal of the globulin, crystallisation was brought about by adding normal acetic acid. The requisite amount was first determined for 5 c.c. portions, acid being added from a micro burette until the first faint permanent turbidity was observed; about 0·21 c.c. were required. Whereas crystals of horse serum albumin usually appear within two hours of acidification under these conditions, we were unable to detect crystals in our preparations of human albumin before the following day. Our experience has indicated that crystallisation of human albumin takes place within narrower limits of hydrogen ion concentration than is the case with horse serum albumin.

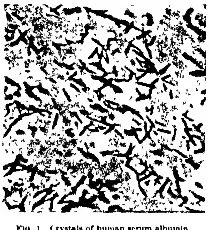

FIG. 1. Crystals of human serum albumin. ×540.

The main bulk of the protein solution was treated by adding slowly the calculated amount of acetic acid. After well defined crystals had formed, the yield was increased by addition of a further amount of acid—half the volume of that first used. Two or three hours later a third addition of acid, equal to the second quantity, was made. The following day the crystals were collected by filtration.

The crystals obtained were readily visible under the 1/6 power of the microscope as small fine needles (Fig. 1). As in the case of horse serum albumin, the crystals dissolved in water to give an opalescent solution which was clarified by filtration, the turbidity being apparently due to lipid associated with the protein.

5 gm. of crystalline albumin was obtained from 300 c.c. of serum, representing a yield of about 40 per cent of its albumin content. Recrystallisation can be brought about by the method described by Adair and Robinson[2].

Stability of the Acetyl Radical

IT is usually supposed that free acyl radicals do not survive the shock of thermal or photo dissociation of the molecule from which they might be formed or, if formed, decompose further before they can react with other molecules to give rise to isolable products. Thus Rice has shown that no diacetyl results from the thermal decomposition of acetaldehyde[1], and Norrish has concluded as a result of his studies of

the decomposition of aldehydes and ketones that both of the bonds between the carbonyl group and the two groups attached to it are broken practically simultaneously, the two groups then, in general, uniting to form a saturated paraffin[1]

During an investigation of the photo-decomposition of di ethyl-peroxide, we have found that the chief products are ethyl alcohol and a greenish yellow substance which has been finally determined to be diacetyl Little if any acetaldehyde was produced, at any rate during the early stages of the decomposition The decomposition was very slow, and although no measurements of the quantum yield have been attempted, a chain reaction would seem improbable

The formation of ethyl alcohol and diacetyl can be accounted for by a mechanism based on that of Haber and Willstätter[3] for enzyme oxidations and also employed by Taylor and Gould to explain the oxidation of ethyl alcohol photo sensitised by hydrogen peroxide[4],

$$CH_3CH_2-O-O-CH_2CH_3 + h\nu \rightarrow 2CH_3CH_2O-$$
$$CH_3CH_2O- + CH_3CH_2-O-O-CH_2CH_3 \rightarrow 2C_2H_5OH + CH_3\dot{C}O$$
$$2CH_3\dot{C}O \rightarrow (CH_3CO)_2.$$

Such a mechanism necessitates a somewhat long-lived acetyl radical In order to obtain further evidence for this, we have examined the non-gaseous products of the decomposition of the three simplest ketones and acetaldehyde In all cases the products were of a greenish yellow colour, which was, however, only faint with diethyl-ketone and acetaldehyde

The products from acetone and methylethyl-ketone yielded with dinitro-phenylhydrazine a few milligrams of a substance almost insoluble in boiling alcohol (and therefore readily separable from the ketone derivative) but which could be recrystallised from pyridine. A derivative with similar solubilities was also obtained from the acetone product with mono-nitro-phenylhydrazine In all cases the physical properties of these derivatives agreed with those of the corresponding derivative of diacetyl. Damon and Daniels have also observed that the liquid products from the photo-decomposition of acetone are coloured

While far from being conclusive, this evidence would seem strongly to suggest that the acetyl radical is much more stable than is usually assumed, and that it possibly plays a significant rôle in the photo-decomposition of acetaldehyde and acetone at room temperature.

Diffusion of Gases through Metals

I have read with interest the letter by Dr Smithells and Mr. Ransley on the diffusion of gases through metals in Nature of November 24 I agree with them that diffusion is dependent on the solubility of gases in metals, and that the approximate proportionality to $\sqrt{P}$ is related to the fact that sorbed hydrogen is not only monatomic, but also ionised, as pointed out by me[1] and by A. Coehn[2]. Further, adsorption on the surface must be distinct from absorption within the metal Absorption must be considered in the study of diffusion, just as Fourier and Poisson took account of specific heat in their classical equations for thermal conductivity

In occlusion and diffusion, the hydrogen is in the form of protons (or deutons). I think the condensation of molecules on the metal surface, due to electrostatic attraction, produces electronic perturbations in the surface metal atoms (as shown by the effect on the photo-electric properties), which facilitates the diffusion of the gas The effect of the adsorbed film can therefore only extend to a distance of one atomic diameter, and the mobility of protons within the metal will not depend on adsorption, but on the particular atomic arrangement of the metal and on the concentration gradient of absorbed hydrogen

An equilibrium exists between the adsorbed gas and the gas absorbed near the surface, in which the two concentrations have a fixed ratio for each gas-metal system. Diffusion therefore depends on many factors. The proportionality between diffusion and $\sqrt{P}$ can be readily interpreted theoretically The deviation from this law can be tentatively explained either by assuming an adsorption pressure threshold on one side and an evaporation pressure threshold on the other side of the metal; or alternatively, as suggested by Smithells and Ransley The hypothesis can be tested by considering the behaviour of palladium towards hydrogen and deuterium

From experiments which are still proceeding and will be published elsewhere, I have been able to show that palladium adsorbs deuterium very considerably from a mixture of hydrogen and deuterium, whereas it is well known that deuterium diffuses very slowly, in comparison with hydrogen, through palladium.

Molecular Spectrum of Cadmium Vapour

In a recent article on the above subject, S. Winston Cram[1] has reported his inability to obtain, either in fluorescence or by excitation with a Tesla coil, a narrow diffuse cadmium band at 2212 He concludes that the band in that region which I obtained some years ago[2], using a pure electrodeless discharge in low pressure vapour, must be due to an impurity

During a year's leave of absence, when working in the astrophysics laboratory of the Imperial College of Science and Technology, I made a careful examination of the molecular spectrum of cadmium Although a full account of this work will be published later, in this letter I should like to direct attention to the following results relating to the origin of the band in question.

(1) As is shown by the spectra reproduced in Fig 1, an arc between cadmium electrodes emits a band at 2212 with an intensity greater than that of the emission band at 2125. This was first noticed in a few cadmium plates given me by H. G. Howell, of Armstrong College, Newcastle-on-Tyne. On trying

an arc myself, it was found that with exposures of the order of one or two seconds, the 2212 band appeared with marked intensity

(2) With a high-frequency (valve) circuit and external electrodes applied to a tube containing cadmium vapour at pressures ranging from 10 mm to 40 mm or higher, the narrow isolated band at 2212 was not obtained In agreement with Cram's results, it was found that the continuous emission on the short wave length side of the resonance line 2288 extended as far as a sharp edge in the neighbourhood of 2212 In two or three spectrograms, however, an increased intensity near 2212 gave the appearance of a narrow band at that place

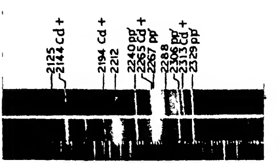

FIG 1 Arc spectra of cadmium with copper arc superimposed on the lower spectrum

(3) In the case of zinc vapour excited with the same high-frequency arrangement, an emission band at 2000 was obtained without difficulty at pressures of the order of 10–12 mm, as is clearly shown in Fig 2. This fact is not irrelevant to the origin of the 2212 cadmium band, because zinc and cadmium have corresponding absorption bands—at approximately 2064 and 2002 for zinc; 2212 and 2125 for cadmium In a note in the *Physical Review*, Winans[3] has stated that the 2212 cadmium and the 2064 zinc bands, both present in absorption, are both *absent* in emission

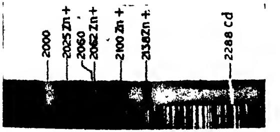

FIG 2 Spectrum of zinc vapour when excited by high-frequency discharge, with external electrodes. Copper arc superimposed

Although my observations as given in paragraph (2) might readily be used in support of Cram's view that the 2212 band is an impurity, it seems to me that the weight of the evidence is in favour of its being a true cadmium band In support of this position, I submit the following arguments.

(*a*) The undoubted presence of 2212 as an emission band in the arc makes it less probable that its appearance, under certain conditions, in an excited tube, is due to an impurity It is not without significance that in both the arc and the early electrodeless discharge showing this band, *pp'* lines are present with considerable intensity These do not occur in Cram's spectra (nor in my recent high frequency discharges), and it may be that the presence of a narrow band at 2212 is associated with the excitation of this group of lines

(*b*) The undoubted presence of a band in both emission and absorption, in the related element zinc, strongly suggests the probability that the corresponding band in cadmium should also be present in emission, as well as in absorption

(*c*) Since there is without question an absorption 2212 cadmium band, it is not a matter of surprise that there should be an emission band also Of course, this does not necessarily follow, but the presence of an absorption band does help to make it less likely that an emission band, found in the same place, is due to an impurity

The origin of certain diffuse bands which occur in the spectra of metallic vapours is, however, not always easy to settle It is only through the co-operation and continued experiment of different workers, using different conditions, that certainty can finally be reached

Structure of Br III

THE spark spectrum of bromine, excited under different conditions, has been photographed over the wave length range λ450–7000, using various instruments, and lines belonging to the doubly ionised atom have been identified

Those experiments have made possible the detection of the structure of Br III which is found in all its characteristic features to be analogous to that of Se II, classified recently by us[1] The intervals of the fundamental term $5s\ ^4P$ are 2587 and 2253 cm^{-1}, and those of $5p\ ^4D$ are 2413, 2070 and 658 units This scheme is however, at variance with the one published by Deb[2], which, we consider, is improbable in many important respects A complete report of the new classifications will be published shortly

Large Sunspot Group of February 1935

ALTHOUGH the sunspot group referred to in NATURE of February 16 (p 260) was not specially large, it was of interest because of its very rapid growth Spectroheliograms in $K_{2,3,2}$ light were secured through thin cloud at the Solar Physics Observatory, Cambridge, on February 5, 6 and 7 On February 5 the group is shown on a plate exposed from 12^h 25^m 18^s to 12^h 26^m 51^s, and as the formation was near the centre of the disc, it must have been recorded very near 12^h 26^m 5^s As no spot was shown on the Greenwich photograph

at 10^h, this fixes the time of formation of the spot to within $2\frac{1}{2}$ hours. On the spectroheliogram the feature was very small. On February 6 there is evidence of very rapid growth; preceding and following spots are clearly shown, and the group extended over about 10° of solar longitude. February 7 still further expansion was shown, with an extent of flocculus of about 15° longitude. Any other observations of this spot group on February 5 during the hours 10^h to $12^h\ 30^m$ would be welcome as affording information of the details of development.

Plasticity of Rock Salt Crystals

THE plasticity of rock salt crystals when immersed in water has been the subject of much attention recently[1]. The fact that the effect takes place more easily in hot water suggests that the rate of solution of the surface is a factor. I have therefore tried bending small plates of rock salt under running cold water from a large tap, and have found that the plasticity is surprising. Under these conditions it is quite easy to make a right angle bend in a plate of rock salt more than a millimetre thick in a matter of seconds.

Points from Foregoing Letters

HIGH-FREQUENCY radio waves such as are used in television (3–20 m. in length), can increase the temperature of certain solutions and of living tissues, and have been used in medical practice (diathermic treatment). Dr. Franz Nagelschmidt describes a method of directing and localising the heating effect by interposing dielectric substances (wax, ebonite) between the electrodes and object, and gives suggestions for practical applications.

Automatic recorders of water-level in deep wells register earthquake shocks. Prof. Perry Byerly and Mr. Francis B. Blanchard describe a water-level recording instrument, and compare its record of an earthquake with that obtained by the usual type of seismograph. They point out that both the primary tremors (P) due to compressional waves travelling through the earth's interior and the later undulations (L) due to compressional waves travelling along the earth's surface were recorded by the water instrument. The intermediate vibrations (S) travelling through the earth's interior and the Love waves were not recorded. This confirms the view that both these latter are shear waves and do not produce changes in volume, which alone affect the water-level.

By means of an improved Svedberg ultra centrifuge rotating 120,000 times per minute and giving a force of 525,000 times that of gravity, Dr. Kai O. Pedersen has succeeded in bringing about changes in the concentration of solutions of substances of low molecular weight. From these concentration changes, deduced from the changes in optical refraction, the molecular weights have been calculated; they agree fairly well with the known values.

Prof. A. Szent-Györgyi in a succinct note states that in the main respiratory process of the muscle, the oxidisation of foodstuffs (or their loss of hydrogen) is brought about by oxidised products of succinic acid; these carry away the hydrogen in the presence of certain enzymes (dehydrogenases).

Mr. Clarence Cottam agrees with Dr. Kathleen Blackburn that the narrow-leaved form of the eel grass is not a hybrid but a different form of *Zostera marina*. From observations on the Atlantic coast from Maine to North Carolina, he concludes that the variation cannot be accounted for simply as due to the depth at which the plant grows, but that other factors such as the age of the plant, temperature, salinity, water currents and conditions of soil or rock bottom may affect the width of the leaves.

The conditions under which the spores of the onion mildew germinate are insufficiently known. Mr. R. McKay has kept the spores under observation for several years, and finds that at the end of three years about one per cent of the spores have their cell wall sufficiently thinned for them to germinate in water in a warm room; the others are still good for another five years' resting stage.

Dr. Muriel E. Adair and Mr. G. L. Taylor have succeeded in obtaining for the first time microscopic crystals of the albumin from human serum (from dropsical patients).

Mr. M. Barak and Dr. D. W. G. Style have obtained diacetyl and its derivatives by means of chemical reactions which suggest that the acetyl radical, CH_3CO- is much more stable than usually assumed. They believe that this radical may possibly be an intermediate product in the photo-decomposition of acetaldehyde and acetone at room temperature, and in other important chemical reactions.

Prof. Tito Franzini points out that the hydrogen atoms which penetrate metals have lost their electrons and consist of positively charged nuclei (protons). Dr. Smithells and Mr. Ransley have indicated that the deviation in the rate of hydrogen from the square root law ($D = K\sqrt{P}$) may be due to surface adsorption. Experiments on the adsorption and rate of diffusion through palladium of ordinary and heavy hydrogen lead Prof. Franzini to assume an adsorption threshold on one side and an evaporation pressure on the other side of the metal.

S. W. Cram, not being able to confirm the observations of Prof. J. K. Robertson that cadmium vapour emits a band of ultra-violet light (wave-lengths around 2212 A.), when excited by an electrodeless discharge, has suggested that Robertson's observations may have been due to an impurity. Prof. Robertson repeated the experiment and obtained only traces of the band in certain spectrograms. He still believes, however, that cadmium emits such a band of light of wave-length 2212 A., and he submits spectrograms to show that it occurs in the arc spectrum of cadmium. Cadmium vapour absorbs light of this wave-length and it is probable therefore that it also emits it.

Research Items

Dual Organisation in Assam. A study of social organisation in Assam by Mr J K Bose (*J Dept Letters, Calcutta University*, 25) is based in part on a review of existing literature, in part on the results of field-work in the period 1931–34 among the Anals, the Aimols, the Lamgangs, the Mantaks, the Marrings and the Memis It is thought that the dual organisation may throw light on the origin of the caste system Among the Aimols, a very primitive tribe, there are two moieties, one superior and the other inferior, each having two phratries and each phratry two patrilineal clans, but the system is in process of disintegration owing to decreasing numbers and the scattered situation of the villages Hence restriction in marriage is slackened, but in social and religious matters the dual organisation is strictly observed Thus the social status of the superior moiety is recognised in all the important offices in the villages The headman, assistant headman and priest all come from the superior moiety The two moieties are also apart in the festivals they observe The Anals, primitive hunter-agriculturists spread over sixteen villages in Manipur, have a typical dual organisation, while the Mantaks, a dwindling group, though in process of disintegration, retain a superior and an inferior moiety, but inferior officers are now drawn from the inferior moiety The Lamgangs, a remote hill-people, show two moieties with only four clans each Here there is evidence of the tendency to arrange the superior moiety in a hierarchy Among the Marrings the dual organisation is of unique type, being based on territorial distribution. The Marring villages are grouped into a set of seven and a second set of five This grouping has taken over the marital functions of the kinship groupings It is clear that in Assam there are definite forms of dual or tripartite organisation of various types and in various stages of disintegration. Assam is, therefore, likely to prove as interesting for the study of early stages of society as Australia or Melanesia

Reproduction in Nudibranchs. Mr Leslie A Chambers has made a valuable contribution to our knowledge of the methods of fertilisation and egg-laying in the Nudibranchiates (*Bull Amer Mus. Nat Hist*, 66, 1934). The forms of the genital ducts are divided into four main types, and taking *Embletonia fuscata* as a typical nudibranch, the author describes the anatomy and histology of its reproductive system There are three passages arising from the hermaphrodite duct—male, female and androgynous A three way valve effecting the selective separation of the spermatozoa from the ova is a feature hitherto undescribed, the author suggesting that it may have a possible general application to the hermaphrodite gastropods in which a separation occurs, that is to say, in most tectibranchs and all nudibranchs There is also a mechanism for erecting the penis which seems to be peculiar to *Embletonia* *Embletonia* was found in enormous numbers on the piles of a bridge near Beach Haven, N J, all the individuals depositing spawn In a few weeks they had all disappeared. This is typical of many nudibranchs, but as some species may be found breeding in the open sea as well as near the shore, it is suggested by the author that inshore spawning grounds are not essential, and that the large numbers of one species sometimes found spawning inland are due to the chance displacement and survival of a few individuals, and their rapid development, no migration taking place Anatomical evidence is given that each individual may pass through repeated reproductive cycles in the same season With so many broods and with every individual of each brood depositing numbers of spawn masses, each single mass containing several hundred ova, there is considerable possibility of deriving the presumed migrations from a single individual cast on the shore by chance

***Calanus* Production in Norway** Mr Jacob D Somme has thoroughly investigated the biology of two species of *Calanus* (*finmarchicus* and *hyperboreus*) based on experimental studies and analyses of samples from the coast of Norway in various seasons (*Fiskeridirektoratets Skrifter Serie Havundersokelser*, 4, 9, 1934) Both species winter in the Lofoten area at great depths *C hyperboreus* particularly is restricted in winter to the inner parts which are very deep, *C finmarchicus* being not so sharply defined in its distribution In spring a vertical migration takes place, and later both species are carried away over the coastal banks in the surface currents The spawning area of *C hyperboreus* is very restricted and mainly dependent upon the extent of the winter area of distribution, the development of the later stages probably depending on low temperatures *C finmarchicus* has a much longer period of spawning and a much larger spawning area Both species may be found together Tables for the identification of all stages are given, and it is shown that the larvae of the two species are not distinguishable by morphological characters, but by measurement of the carapace rather than total length Unfortunately, the paper by Dr S G Gibbons on *Calanus finmarchicus* (Fisheries, Scotland, Sci Invest, 1933 No 1) was published too late for it to be used, as was also Dr Nicholls's study of the life history of *Euchaeta* (*Proc Roy Soc. Edinburgh*, 1934)

'Plaster Mould' Diseases of Mushroom Beds A very useful article by Mr W M Ware appears in the *Gardeners' Chronicle* of December 22 and 29, 1934 It describes two 'weed' fungi which are likely to grow on mushroom beds, to the detriment of the edible fungi Both of the undesirable organisms are known as 'plaster moulds', since they produce a white, powdery covering similar to a dusting of plaster or lime The white plaster mould (*Oospora fimicola* *Monilia fimicola*) was known by English growers some time before it was recorded by the mycologist It also occurs in France and the United States Characters of the species are given in detail, and its occurrence described It appears on beds just before they are ready for spawning, and also grows upon the covering of soil or 'casing', which is applied after the spawn has been added Circumstantial evidence indicates that the fungus is introduced by the manure. The brown plaster mould (*Papulaspora byssina* or *Myriococcum praecox*) originally made its appearance in the United States in 1923, but has now appeared in Great Britain This disease appears at the same time, and under similar conditions to the white plaster mould, but is not usually so harmful.

It first produces a white superficial mycelium, which quickly becomes cinnamon brown except at the edges. The brown part bears 'bulbils', or aggregations of hyphal cells, which seem to function as the sole reproductive bodies of the fungus. The brown plaster mould also seems to be introduced by the manure.

Traps of the Bladderworts. It is refreshing to find a genus of plants, the bladderworts (*Utricularia*), which scores so admirably off the animal kingdom. Prof. F. E. Lloyd (*Biol. Rev.*, 10, 1, 72, 1935) gives an extremely interesting account of the various kinds of traps—really modified leaves—and especially of the entrance mechanisms. The swiftness of the action is remarkable. By making use of motion photomicrography speeded up to 160 frames per second, the whole action falls within the sequence of five frames, the opening phase falling between two frames and the slower closing phase occupying the rest of the time. The entrance mechanisms of the traps are shown to be far more complicated and more delicate in their adjustments than has heretofore been thought, and are shown to be purely mechanical in action.

Clean-up of Gases by Getters. The process of removal of gas by the action of electropositive metals such as magnesium and barium is of great technical interest since it is much used in the evacuation of vacuum devices. A. L. Reimann (*Phil. Mag.*, Dec. 1934) has investigated the process for the 'getters' magnesium, calcium and barium and a number of common gases. Some clean-up occurs when the 'getter' is first volatilised on to the walls of the vacuum vessel (dispersal gettering); there is then some absorption of gas by contact action and the rate of removal is accelerated by maintaining an electric discharge in the gas. The 'dispersal gettering' may be treated as 'contact gettering' by a series of freshly formed getter surfaces. The contact gettering is more effective with barium than with magnesium or calcium, and is greatest when a black deposit of finely divided barium was formed by dispersal in the presence of gas. In most cases of contact gettering, the getter can take up much more gas than would cover its surface with a monomolecular layer—the gas seems to diffuse into the interior of the deposit. The gettering is usually favoured by a rise in temperature. The gas absorbed by a getter may be liberated again by heating, by displacement by another gas, or by impinging electrons or ions. In one of the experiments on a valve, if the anode potential was applied before the filament was heated, the getter acquired a positive potential and the vacuum deteriorated by electron bombardment of the getter. If the filament was heated and anode potential then gradually increased, the floating getter deposit acquired a different, lower, stable potential and the vacuum began to improve by clean-up. In electric discharge gettering, the getter removes particles such as positive ions and metastable molecules, and in some cases these form chemical compounds which are more stable than the products of simple contact gettering.

Oxygen Isotopes in Meteorites. An investigation on the relative abundance of the oxygen isotopes O^{16} and O^{18} in stony meteorites (S. H. Manian, H. C. Urey and W. Bleakney, *J. Amer. Chem. Soc.*, 56, 2601; 1934) by a method involving the conversion of the combined oxygen to water and then, by electrolysis, to oxygen gas, showed that the specific gravity of the water indicated, within an experimental error of 29 per cent, in the ratio $O^{16}:O^{18}$, the same isotopic composition of the oxygen from three stony meteorites (Mocs, Kuyahinya, Homestead) as from terrestrial granite and from potassium chlorate. Relative abundances of the isotopes in the oxygen gases were investigated by the vacuum mass spectrograph and the same results were found, the experimental error in $O^{16}:O^{18}$ being reduced to $\pm 2 \cdot 5$ per cent. The value $514 \pm 13 \cdot 1$ is submitted for the absolute abundance ratio $O^{16}:O^{18}$ for both terrestrial and meteoric oxygen. The agreement of this result with other mass-spectrographic determinations is compared, and the discrepancy with the band spectra value is pointed out. The average value of the mass-spectrographic determinations by the four different researches (omitting the results of Kallmann and Lasareff) is 517 ± 10.

The Methylene Radical. By the thermal decomposition of diazomethane carried in a current of ether or butane below 500°, the free methylene radical, $.CH_2$, appears. It removes mirrors of tellurium, selenium, antimony and arsenic from the tube. In the case of tellurium, a red solid polymer of telluroformaldehyde, $(HCHTe)_n$, is produced, whereas free methyl forms a volatile red liquid, dimethyl ditelluride, $CH_3TeTeCH_3$. F. O. Rice and A. L. Glasebrook, who report these results (*J. Amer. Chem. Soc.*, 56, 2381, 1934), point out that they are not in agreement with current ideas on the nature of the methylene radical, most of which are based on Nef's premise that carbon compounds readily undergo a primary decomposition into a stable smaller molecule and a radical containing bivalent carbon, and some lines of evidence which would indicate that methylene should have a peculiar stability resembling that of a molecule rather than that of a free radical. At temperatures above 650°, it was found, but below the decomposition point of ether, only methyl groups were found; the methylene radical is apparently a highly reactive fragment of short life.

Meridian Observations of Faint Stars in Selected Areas. In the *Annalen van de Sterrewacht te Leiden*, 25, 4, Dr. C. H. Hins publishes a general catalogue of positions and proper motions of 1190 standard stars in areas 2–115 of Kapteyn's plan of selected areas. This work is the reduction to a uniform system, and combination, of the work of five observatories taking part in Kapteyn's plan, namely, Leyden, Berlin-Babelsberg, Bonn, Paris and Strasbourg. The positions are in every case modern meridian circle observations of right ascension and declination, and proper motions have been found by comparison with old observations; but it is found that the modern precision so much exceeds the old that better proper motions would be obtained by repeating the observations in a few years time than by combining new with old observations. The author has reduced all the observations to the Leyden system as fundamental. (This system is in full agreement in R.A., and in very close agreement in Dec., with the P.G.C. system.) The magnitudes of the stars lie for the most part between $7 \cdot 6^m$ and $9 \cdot 8^m$, the average magnitude being $8 \cdot 5^m$. The unit of weights is, on the average, $\pm 0 \cdot 0275^s \sec \delta$ and $\pm 0 \cdot 44''$ for R.A. and Dec. respectively, the weights attached to individual stars being for the most part from 2 to 10. Dr. Hins may be very heartily congratulated on the completion of this part of Kapteyn's plan of selected areas.

Effect of the Earth's Magnetic Field on Cosmic Rays in the Stratosphere

By MAX COSYNS, Physical Laboratory of the "Fondation Medicale Reine Elisabeth", Brussels

DURING the last ascent of the balloon *F N R S* (August 18, 1934), we had the opportunity of measuring with precision the intensity of cosmic rays at altitudes of about 12,000 m, 15,000 m and 16,000 m, by means of the ionisation chamber (Kolhörster type) which was used during our previous ascent with Prof A Piccard (August 18, 1932)

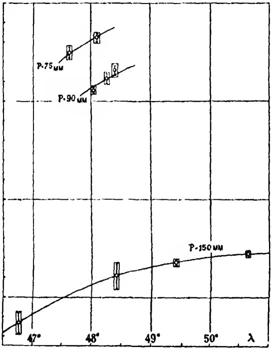

FIG 1

The comparison of these data, and also those of the previous ascent, shows clearly an effect of the earth's magnetic field

From our sixty values of ionisation intensity (J), obtained at pressures of the atmosphere (P) ranging from 73 mm to 170 mm of mercury, and between 46° and 51° of north magnetic latitude (λ), we can deduce functions relating J to P, and J to λ (Figs 1 and 2)

In Fig 1, the circles give the mean values, the vertical lines give the probable error calculated from the dispersion of individual observations, the rectangles give the total probable error, calculated from the dispersion of individual readings, and from the precision of measurements of atmospheric pressure and geographical position The atmospheric pressure was measured by means of two mercury barometers, the geographical position was determined by vertical photography with a Leica camera and infra red films (precision = 30″) or by astronomical observations when the clouds below were too thick for photography (precision = 10′) The geomagnetic latitude was calculated taking 78° 30′ N and 69° 8′ W. as the co-ordinates of the pole of the principal earth-magnetic doublet[1]

Through the four points of Fig 1 which correspond to a pressure of 150 mm., we can draw a smooth curve; if we multiply the ordinates of that curve by reduction coefficients obtained from Fig 2 (J vs P), for pressures of 90 mm and 75 mm, we obtain the two upper curves of Fig 1, fitting the corresponding points within the probable error

A comparison of these results with the theoretical curves of Lemaître and Vallarta[2] shows perfect agreement if we assume that more than 80 per cent of the ionisation in the stratosphere (for $\lambda > 50°$) is due to a charged corpuscular radiation of magnetic hardness $X_0 = 0{\cdot}30 \pm 0{\cdot}02$, and to the secondaries emitted by that radiation in the earth's atmosphere Within the limit of experimental error, this is in perfect accordance with the results of Clay[3], who found $J = 12$ at $P = 150$ mm. and $\lambda = 48°$, and those of Clay and Compton[4], showing a maximum curvature of the (J vs λ) curves for about $\lambda = 50°$, at pressures between 450 mm and 760 mm

The analysis of our (J vs P) curve (at $\lambda = 48°$) (Fig 2) by means of the Gross Lenz method[5], gives a transformed curve $P\Psi_p = PJ_p - P^2 dJ_p/dP$, showing three maxima, corresponding to about 130 mm, 190 mm and 400 mm of mercury Although their position is not defined with precision, the existence of the maxima seems to be beyond doubt, the amplitude of the corresponding variation of J being more than three times larger than the probable error

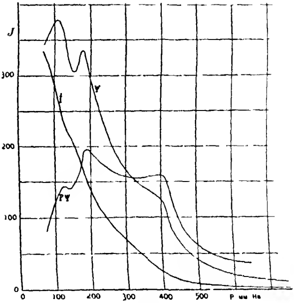

FIG 2

These three maxima show the existence of, at least, three soft components in the cosmic radiation, with ranges of the order of 130 mm, 190 mm and 400 mm of mercury But, as the shape of the (J vs λ) curve requires a very narrow range of magnetic hardness *for the primary rays, only one of these components, if any, is a primary one*

To my idea, the hypothesis according best with the observed facts would admit a primary radiation consisting of two corpuscular components A and B, of respective magnetic hardness $X_{0A} = 0{\cdot}30$ and $X_{0B} = 0{\cdot}45$. The A component, positively charged, would give secondaries (electrons and positrons) of

discrete energy distribution, of which the hardest three components would have absorption coefficients of the order of 0·0018, 0·0039 and 0·0057 gm^{-1} cm^{2}. The B component would give secondary radiations of the same nature as the secondaries issuing from A, with an energy distribution as yet unknown, but corresponding to an absorption coefficient of the order of 0·0027 gm^{-1} cm^{2}.

The A and B components may perhaps be identified with Regener's components H_1 and H_2, their respective magnetic hardness X_0, calculated by the method proposed by Heisenberg[6], gives the right order of magnitude, if we assume that the primary rays are α particles. If we suppose that X_{0A} is exactly equal to 0·30, we find X_{0B} = 0·50, this gives a good reproduction of Clay's curves (J vs λ) at sea-level. However, Regener's values for the respective intensity of those components at the earth's surface are not in good agreement with our hypothesis. But it must be noted that the calculation of those intensities requires many assumptions about the secondary emission mechanism, it might be, therefore, that a new discussion of deep water measurements, with different assumptions, would give values more in accordance with magnetic effects.

Our hypothesis is also in quantitative agreement with the east-west asymmetry observed by H. Johnson and others. Quantitative divergences from those measurements may be attributed to the fact that we know little about the angular distribution of secondaries around the primary direction, and also to the fact that no account has been taken of the atmospheric electrical field effect. This effect is not negligible for the softer part of the radiation responsible for east-west asymmetry, as a calculation of a lower limit of the variation of the angle of incidence β of rays gives $\Delta \tan\beta = \pm 515\, E^{-1/2}$ (where E is the energy of the ray, in electron-volts).

A more detailed account of the experiments described above will be published soon. The measurements were made possible by the help of the Belgian "Fonds National de la Recherche Scientifique", with the advice of Prof. A. Piccard and with the very efficient help of N. Van der Elst.

National Water Policy in Great Britain

THE recently issued report of the Joint Conference of the Institution of Water Engineers, the British Waterworks Association and the Water Companies Association on national water policy is a document of considerable interest, dealing, as it does, with a matter of vital public importance which has been debated for some time past in the Press, in Parliament and in various other quarters. It is to be regretted, however, that the Committee to which the question has been referred, appears to have been composed of representatives or consultants of water supply undertakings (mainly municipal) for domestic purposes, and, so far as can be gathered from a scrutiny of the names of the members, there was no direct representation of the commercial and industrial users of water, as also of other interests no less vitally concerned in the exploitation of the country's supplies. Land drainage and the prevention of floods, although necessarily bound up in any national water policy, evidently did not come within the purview of the Committee. Neither has any consideration been given to the aspects of the matter as affecting fisheries, navigation, canal sources of supply, and the like. The report is concerned solely with the allocation of water supplies to domestic uses.

The first matter dealt with is the proposed establishment of a 'water grid', put forward some time ago by Mr. Alan Chorlton, M.P., and advocated by him in a presidential address to the Institution of Mechanical Engineers in October 1933. This scheme, which is based on the analogy of the electricity grid, is condemned in the report in no uncertain terms. "We are definitely of opinion," states the Committee, "that as regards water supply, such a system is totally unjustifiable from every point of view, and especially in its economic aspect." The proposal is analysed in detail in a memorandum attached as an appendix to the report, summarising the objections under eight heads, which, for reasons of space, cannot be discussed here. Although, perhaps, controversial in some respects, they are weighty in substance and the cumulative effect is decidedly condemnatory. The Committee expresses itself as quite satisfied with the *status quo*. "In the unusual difficulties resulting from the recent exceptional drought, the water undertakers of this country have generally proved themselves well qualified to protect the true interests of their consumers and to meet their obligations to the public at large." Accordingly, the Committee is equally averse to the nationalisation of water supplies under a National Water Board. It considers the Ministry of Health to be the proper central water authority, and puts forward a proposal to meet the conditions at present prevailing by the "creation of a distinct, separate and specialised Water Department of the Ministry of Health", with various powers which are set out in detail.

It is perhaps not surprising that a Committee, constituted as stated above, should affirm its faith in the Ministry of Health as the sole suitable arbiter and dispenser of water throughout the country, but for the reasons already given, this can only be considered as a one-sided view. Other interests will scarcely be disposed to agree to such a monopoly. The British Association Research Committee on Inland Water Survey, whose investigations are referred to non-committedly, has been urging the establishment of a national survey of water supplies on a purely scientific basis under the Department of Scientific and Industrial Research. The Government, while acceding to the overwhelming demand for a survey, has seen fit to disregard this recommendation and to place the survey in the hands of the Ministry of Health. It is difficult to appreciate the grounds upon which this step has been taken, since no analogous example from the practice of other countries have been cited in support of it. That the Ministry of Health, the proper functions of which are clearly indicated in its designation, should intervene in other spheres where its action and control might be misguided and detrimental, is a matter greatly to be deprecated.

BRYSSON CUNNINGHAM.

The Process of Coagulation in Smoke*

IN contradistinction to hydrosols, smokes are unstable systems Their particles cohere when brought together by Brownian agitation, and this process of coagulation proceeds spontaneously until the system becomes a coarse suspension of complex aggregates, and finally sediments rapidly

In recent years, special methods have been developed for counting the number of particles in many types of smoke, and the process of coagulation has been studied quantitatively in a variety of systems It has been found experimentally that the decrease with time of the number of particles in a smoke is given to a first approximation by the expression $1/n - 1/n_0 = Kt$, where n is the number of particles present in a given volume at time t, n_0 the initial number and K a constant As is well known, an expression of the same form is valid for the recombination of ions, but in a normal smoke the combination of particles to form aggregates is only influenced slightly, if at all, by electrical charges

A comparison of the coagulation constants or K values for different smokes of about the same mass concentration shows that they vary between comparatively narrow limits from about $0\ 8 \times 10^{-9}$ cm ^{3} sec $^{-1}$ in the case of oxide smokes formed in the electric arc to $0\ 50 \times 10^{-9}$ cm ^{3} sec $^{-1}$ for a standard smoke of stearic acid of mass concentration of 15 mgm per cubic metre

The structure of the aggregates and the nature of the material do not, so far as is known at present, exert any marked effect on the rate of coagulation, which appears to be a purely physical process dependent on the chance encounter of particles in Brownian motion Experimental evidence, however, shows that the coagulation constant increases rapidly when the average size of particle falls below 1×10^{-5} cm radius, and it increases also with the degree of heterogeneity of the smoke By a careful study of the conditions under which a smoke is formed, Patterson and Cawood have prepared disperse systems of stearic acid particles which initially approach to uniformity in size This was accomplished by dispersing the heated solid in a rapid blast of hot air, and by this means diluting rapidly the concentrated smoke before coagulation had proceeded far Such smokes are readily reproducible and form standard systems which coagulate at the same rate and contain the same number of particles, and since they form compact aggregates they approximate in character to ideal systems of spherical particles

The well known theory of von Smoluchowski, which has been confirmed experimentally for the coagulation of sols by the comprehensive researches of Tuorila, when modified so as to apply to aerial systems, enables the coagulation constant of a homogeneous smoke to be calculated from first principles Patterson and Cawood have shown that when the experimental data for these 'blown smokes' are interpreted rightly, a remarkably close agreement between theory and experiment is obtained Theory also indicates that whilst in sols undergoing quick coagulation the rate should be independent of size, in aerial systems it should increase as the particle size diminishes, a prediction in entire conformity with experiment

Both in sols and aerosols, theory shows that heterogeneity must increase the chances of encounter between particles, but although in sols it has been possible to check experimentally the extension of von Smoluchowski's theory proposed by H Muller, for heterogeneous smokes theory so far has not proved more than a qualitative guide

The study then of smokes affords strong confirmatory evidence of the validity of Smoluchowski's theory, and lends support to the view that this continuous process so characteristic of these systems is akin to the quick coagulation of sols in the presence of electrolytes, and points to the probability that in both classes of system every collision between particles is effective It must, however, be noted that the coagulation constants for systems of fine suspensions in water and in air are widely different, the latter being about a hundred times as great as the former But since the time taken to reduce the original number of particles in a system to any given fraction depends on the number as well as on K, the disappearance of particles by coagulation in town fogs and other polluted atmospheres will be slow

* Substance of the Liversidge Lecture delivered by Prof R Whytlaw-Gray, O B E, F R S, before the Chemical Society on February 14

British Industries Fair, 1935

IN the account given last year in NATURE of the 1934 British Industries Fair, it was described as the largest national trade fair in the world The 1935 Fair, which opened in London on February 18, is even larger than its immediate predecessor —a reflection, it may be hoped, of increasing prosperity in the nation's trade. At Olympia the lighter industries occupy every available square foot of exhibiting space, while the textile and furnishing sections at the White City are larger and more fully representative than ever. The main object of the Fair is, of course, a commercial one ; the most welcome visitors are buyers But the Fair has, undoubtedly, an educational value, for it presents to the visitor, in an attractive and accessible form and in a condensed space, a general survey of the results of the nation's manufacturing industry. Moreover, every changing phase in the tastes and habits of the people is reflected in such a collection of manufactured articles as is to be found at the Fair The removal of much that is tedious and unnecessary from domestic work is indicated by the increased popularity of chromium-plated ware and of stainless steel and stainless silver articles, and by the space allotted in the Fair to the exhibition of devices for domestic mechanisation The exhibition in larger quantities of open-air equipment of all kinds indicates that increasingly the leisure of the people is being used in healthy pursuits

At Olympia, the exhibition is, as previously, divided into sections according to industries, and it is perhaps symbolic of the increasing recognition of the co operation which must exist between science and industry, that the section devoted to the exhibition of the products of the Scientific and Optical

Instruments Group should occupy a prominent position near the main entrance to the Fair. The exhibits of the various firms in this section are placed so compactly together that a visual impression is conveyed of the co-operation and joint effort which is to be found among the members of the industry. The instruments shown are mostly optical in character, and one is reminded again of the large part played in scientific and industrial life by the products of the optical firms. Besides the normal instruments for laboratory equipment, special instruments are shown for use in aeronautics, astronomy and meteorology, together with those specially adapted to nautical and surveying requirements. One is impressed by the success which has been attained in so many of the instruments in combining the robustness required for industrial use with the necessary delicacy of movement.

Few things have been more striking of recent years than the development of long-distance telegraphy. It is but a short time ago that the first photographs were telegraphed from Australia to England, and quite recently a cinematograph film was exhibited in England showing events which had taken place but a few hours earlier in Australia. The exhibit of Cable and Wireless Ltd. is, on this account, of special interest. The modern system of long distance telegraphy is admirably shown at its stand. The types of apparatus used for this work are presented in actual operation, and a study of the receiving and transmission units, magnifying relays, distortion removers and regenerators gives the visitor a clear idea of the inventive research which has enabled long-distance telegraphy to become part of his daily life. Realism is added to the demonstration by the fact that a written telegram, handed in at one end of the stand, is delivered as an automatically typed message at the other end after having passed through the complete system.

The chemical industry provides another example of the co-operation which may exist between firms in the same industry to their mutual benefit. Messrs. Hopkin and Williams and British Drug Houses Ltd. have combined their knowledge and experience to further the production of chemical reagents of an exceptionally high standard of purity, and these reagents are being exhibited by the firms. The very large field covered by the activities of Imperial Chemical Industries Ltd. is well illustrated by the fact that this firm has thought it worth while to devote a large portion of its space at the Fair, not to the display of its products, but to a presentation of its sales machinery. By means of interesting maps, the way in which chemical products enter into almost every phase of industry throughout Great Britain is clearly demonstrated. The same firm is making a special point of the hydrocyanic acid method of fumigation, especially for the cleansing of vermin-infested houses. Great success is claimed for this method of fumigation, and specimens of the fumigant and of its prospective victims are shown. The same fumigant has a variety of other and more pleasant uses, the removal of fruit-damaging insect pests from orange groves being specially emphasised as being of interest to overseas visitors.

Of the other industries represented at the Fair at Olympia, no section is more attractive, and certainly none more colourful, than that of the glass and pottery trades. A more perfect blending of utility and beauty can scarcely be imagined. It is perhaps fitting that the products of possibly the most ancient craft represented at the Fair should appear so near to perfection. The beauty of the exhibits is enhanced by the excellent lighting, and the stands furnish an example of the use of modern lighting effects to improve the display of goods. Quite near to the glass and pottery section, on the floor above, is a large area devoted to plastics, and it is not uninteresting to compare the products of this very modern industry with those of the very ancient one mentioned above. The increasing use which is being made of plastic materials is reflected in the very large increase of space occupied by the plastic group. In this industry the gap between laboratory experiment and workshop practice has been most effectively and rapidly bridged.

The fact that in London alone more than fifteen hundred firms are exhibiting almost every variety of manufactured articles makes it obviously impossible in a limited space adequately to describe such a Fair. In addition to these firms, one hundred and thirty four inventors are displaying for the first time to the purchasing public the results of their ingenuity, which range from rubber contrivances for the prevention of housemaid's knee to a mechanical device for 'breaking-in' new pipes.

At the White City every phase of textile manufacture is represented; whilst the furniture section at the same place presents a wide field of interest to those concerned with the evolution and modern developments of furniture. The Fair remains open until March 1. The Engineering and Hardware Section opens in Birmingham on May 20.

University and Educational Intelligence

CAMBRIDGE.—At the Congregation of the Regent House a grace will be submitted appointing Prof. G. H. F. Nuttall, Magdalene College, emeritus professor of biology, Prof. E. D. Adrian, Trinity College, Prof. R. C. Punnett, Gonville and Caius College, Balfour professor of genetics and Mr. C. Forster Cooper, Trinity Hall, University reader in vertebrate zoology, delegates from the University to the tercentenary of the National Museum of Natural History in Paris next June.

At Newnham College the Henry Sidgwick Memorial Lecture will be delivered on March 9 in the College Hall at 5 p.m. by Sir John Russell, director of the Rothamsted Experimental Station. The subject of the lecture is "The Impact of Science on the National Life".

THE thirteenth Unity History School will be held in Rome on April 15–22. The subject of the meeting will be "Science in the Modern World". On April 15, the inaugural lecture entitled "Science and Philosophy" will be delivered by Prof. F. Enriques, president of the School of the History of Science, University of Rome. Other lectures will be delivered by Mr. F. S. Marvin, director of the Unity History Schools, Prof. H. Dingle, Dr. W. A. Parr, Prof. E. Radl, Dr. C. H. Desch, Prof. C. Formichi, Dr. G. Sarton, and M. Lheritier. Several discussions have also been arranged. Further information can be obtained from Mrs. K. E. Innes, 29 High Oaks Road, Welwyn Garden City, Herts.

VOCATIONAL guidance service finds a valuable auxiliary in the *Journal of Careers* (monthly, 1*s*.). The December issue contains "The Prospect in

Surgery" by Sir Holburt Waring, a sequel to an article in the preceding month by Sir Humphry Rolleston on general medical practice and the main branches of specialisation. Sir Holburt gives expression to a view which, he says, will be considered in many quarters as revolutionary, namely, that the methods which are beginning to be practised in industry—selection on account of special aptitude, mentality and physical characteristics, might well be applied in surgery and also in the various branches of medicine. Considerable space is devoted to civil aviation in addition to the first of a series of articles on the opportunities of new careers which the development of flying will offer, there is a summary of an address by Prof Sutton Pippard to the Royal Aeronautical Society on the training of an aeronautical engineer Veterinary surgery as a profession for women is discussed by Beatrice Lock, this being the second of a series of articles on "Women in the Professions" Another useful series deals with the prospect for public school and secondary schoolboys in the iron and steel industry, the article in the December issue being on technical and commercial posts. Lieut -Col Levey, managing director of the West African Information Bureau, writes on the prospects for British commerce in West Africa The *Journal* has not failed to direct attention to the complaint, voiced in the presidential address to the Association of Special Libraries and Information Bureaux by Sir Richard Gregory, of the inadequacy of the arrangements made for the treatment of scientific news in daily and weekly newspapers New fields of work should be opened up for science graduates with journalistic ability.

Telford and the Institution of Civil Engineers

At a special meeting of the council of the Institution of Civil Engineers held on February 23, 1835, the following extract from the will of Telford was read. "To the president for the time being of the Civil Engineer Institution in trust, the interest to be expended in annual premiums under the direction of the Council, 2,000£ "

"All my scientific books, book cases, prints and such drawings, as my executors shall consider suitable, are to be delivered to the Civil Engineer Institution for its use and benefit, on condition, that all those articles, as well as the books, prints and drawings, shall, in case of the said Institution being discontinued, be delivered to the Royal Society, Edinburgh, for its use."

The council resolved that the premiums should be both of an honorary and pecuniary nature, and that the honorary premiums should consist of gold, silver and bronze medals, and that in the distribution of premiums no distinction should be made between natives and foreigners.

The Zoological Society

On February 24, 1835, Owen read a paper to the Zoological Society entitled "Description of a Microscopic *Entozoon* infesting the Muscles of the Human Body". He said that upwards of fifteen different kinds of internal parasites were already known to infest the human body, but none had been found of so minute a size, or existing in such astonishing numbers, as the species he described The muscle of bodies dissected at St Bartholomew's Hospit had been more than once noticed by Mr Wormal the demonstrator of anatomy, to be beset wit minute white specks, and this appearance hav again been remarked in the body of an Italian, age forty-five years, by Mr Paget, a student at th hospital, who suspected it to be produced by minu Entozoa, the suspicion was found to be correct, ar Owen had been furnished with portions of th muscles for examination An account of his observ tions was published in the *Philosophical Magazi* of June 1835

University of London

The annual general meeting of the proprietors the University of London was held on February 2 1835 The report expressed satisfaction at the pro pects of the institution, and stated that the numb of students in the Faculty of the Arts and La during the year had increased from 122 to 137, th number of students in Medicine from 347 to 37 The number of pupils in the junior school ha increased from 284 to 303 The total receipts f 1833 had been £9,890 3*s* 0*d* and for 1834 £9,9 16*s* 8*d*

The Natural History of Wasps

A paper on the natural history of wasps was rea on February 27, 1835, by the Rev E T Bigge, Merton College, to the Ashmolean Society of Oxfor The object of the paper, said the author, was t correct the mistakes into which several writers ha fallen, and to state the results of his own observatio on two species, *Vespa vulgaris* and *Vespa Britannic* The former, he said, was common in all parts of th kingdom, the latter, though occasionally met wit in the southern counties of England, was abundant i the northern districts, and in Scotland, as well as i the northern parts of Europe Having directe attention to the points of difference in the two specie the author went on to state some interesting fact relating to both species Societies of wasps, as bees, consist of three different classes of inhabitant males, females and neuters The neuters, or im perfectly developed females, are the common wasp which infest our houses and gardens, and form th majority of the colony The author had never see a nest of either species in which he had not observe after 9 o'clock, in the summer months, a sentin watching the entrance to the nest A ground nes has two apertures, one for entry and one for exi It is curious that if one stops up a wasps' nest, th returning wasps will not sting the aggressor, whil those which escape from the inside will attack hi instantly

Weather in the United States

In the *Mechanics' Magazine* of February 28, 183 it was stated that: "The winter in America ha been one of almost unprecedented severity. I January the thermometer sunk at New York t *5° below zero—at Baltimore to 10°—at Washingto* to 16°—at Albany to 32°—at Montreal to 35° an at New Lebanon in Columbia county to below 40° the mercury in the bulb being 'congealed and fo some time immovable'. The harbours of Portland Newburyport, Boston, New Bedford, New Haven Philadelphia and Baltimore have all been froze over; some of them hard enough to bear carriages

Societies and Academies

LONDON

Royal Society, February 14 G. BARRY, J W COOK, G A D HASLEWOOD, C L HEWETT, I HIEGER and E L KENNAWAY The production of cancer by pure hydrocarbons (3) Tests for cancer-producing activity on the skin of mice have been carried out with a number of pure compounds of known molecular structure, most of which have been polycyclic aromatic hydrocarbons In all, some 140 different compounds have now been tested Of these, 69 are related to 1 2-benzanthracene and 25 of them have given positive results 1 2-benzanthracene itself has very little carcinogenic activity, but such activity is shown by derivatives in which substituents (saturated alkyl groups or additional rings) are attached to positions 5 or 6, or both The most active so far encountered is methylcholanthrene, a hydrocarbon which was obtained by simple chemical means from the deoxycholic acid of bile In this way a direct relationship has been established between the carcinogenic compounds and some normal constituents of the body Of 71 compounds not related to 1 2 benzanthracene, 65 have given completely negative results Of the 6 compounds which gave positive results, only 3 4-benzphenanthrene had considerable activity The remaining 5 compounds gave only 10 tumours (2 epitheliomas and 8 papillomas) in 360 mice By way of contrast the 25 carcinogenic compounds *related* to 1 2-benzanthracene gave 437 tumours (335 epitheliomas and 102 papillomas) in 1,220 mice C H WADDINGTON, J NEEDHAM, W W NOWINSKI and R LEMBERG Studies on the nature of the amphibian organisation centre (1) Chemical properties of the evocator An evocator, that is, a substance capable of causing the ectoderm of the amphibian gastrula (*Triton* spp, axolotl) to differentiate into neural tissue, has been obtained in ether extracts of whole newt bodies and of mammalian liver The active substance is present in the unsaponifiable fraction, and in the part of that fraction precipitable with digitonin It comes out with the cholesterol if the unsaponifiable fraction is allowed to crystallise from alcohol in the cold, and is probably of a sterol-like nature An active ether soluble substance, which is also precipitable with digitonin, has been isolated from crude preparations of glycogen The whole of the evocating activity of glycogen may be due to the admixture of this substance C H WADDINGTON and D M NEEDHAM Studies on the nature of the amphibian organisation centre (2) Induction by synthetic sterol-like substances Certain synthetic hydrocarbons have been implanted into young amphibian gastrulæ Inductions of neural tissue have been performed by 1 9-dimethylphenanthrene, 9 . 10-dihydroxy-9 10-di *n*-butyl-9 : 10-dihydro 1 . 2 . 5 : 6-dibenzanthracene, and 1 . 2 5 . 6-dibenzanthracene The first two of these are œstrogenic and the third carcinogenic. There is therefore probably a group of evocating substances which overlaps with the group of œstrogenic and carcinogenic substances This provides the first satisfactory evidence that more than one substance is capable of evocating, and suggests that the naturally occurring evocator is a sterol like substance

EDINBURGH

Royal Society, February 4 W L BRAGG The new crystallography (Bruce-Preller Lecture) The mapping of atomic arrangement by X-ray analysis first applied only to crystalline solids but more recently extended to glasses, liquids and gases, has now been pursued for more than twenty years A review of the influence which this new knowledge has had in many branches of science is impressive Some idea of this influence can be gained by taking examples in inorganic chemistry, organic chemistry, mineralogy, metallurgy and biochemistry Though such isolated examples are only random soundings over a wide area, they serve to give an impression of the precision, simplicity and novelty of outlook which a knowledge of the actual atomic arrangement introduces They also indicate the fascinating lines of research which are opening out ahead

Problems of Human Nutrition

OF the two factors which together mould the individual, heredity and environment, modern knowledge is attributing more and more importance to the latter; in fact, as Sir Frederick Gowland Hopkins pointed out in his Sir Henry Trueman Wood Memorial Lecture delivered before the Royal Society of Arts on February 6, although inheritance must set definite limits to the possibilities before each individual, environmental influences can decide whether, within those limits, the highest level possible is reached, or only a level which may be much lower than this. Among all the demands which the body makes on its environment, that for its food is of outstanding importance, and it is to-day becoming recognised that right nutrition, especially in early life, may profoundly affect the well-being and social value of the individual Knowledge obtained by scientific inquiry is beginning to take the place of instinct and appetite aided by very slowly growing transmitted experience There is still to be combatted the idea that the race, having survived through the ages without such knowledge, can continue to thrive without making any practical use of it but mere survival of a race is no proof that the majority of its members have ever lived in optimal conditions, or have ever displayed to the full their innate capacities

Briefly, the essential constituents of a diet are proteins of good biological value, fats, carbohydrates, minerals and vitamins The energy value should be not less than 3,000 calories *per diem* for the average man -probably it would be better to take the higher figure of 3,400 calories as suggested by the Committee of the British Medical Association The value of a protein depends on how far its constituent amino-acids resemble those of the body in nature and grouping, so that animal proteins are of higher biological value than vegetable Although fats and carbohydrates are interchangeable as sources of energy, yet both are necessary in the diet. Fats cannot be properly utilised in the absence of carbohydrates, and it is now known that certain fatty acids are as essential constituents of a diet as some of the amino-acids The relationship of the mineral elements and the vitamins to different diseases is now well known. To sum up, scientific research during the last two decades has shown that nearly forty individual substances must be

present in a food supply to make it completely adequate

It is not always realised how easily a diet, generally considered satisfactory, can be improved, or how easily experimental alterations in a food supply, carried out without complete knowledge of what constitutes a proper diet, may spell disaster Corry Mann investigated the effect of adding $1\frac{3}{4}$ oz of butter or one pint of milk daily to the ordinary diet of boys in an institution The average weight and height increases for the three groups, on diet alone, diet plus butter and diet plus milk, were, in one year, 3·85 lb and 1 84 in , 6·3 lb and 2 22 in , and 7 lb. and 2·63 in , respectively Again, Christ's Hospital School, by utilising the results of the modern science of nutrition, has been able, during the past twenty years, to increase the height and weight of the boys until they are now several inches taller and several pounds heavier than boys of similar age who have not had the benefit of a sound diet During the War, when food was short and of poor quality, and substitutes had to be used, the Christ's Hospital records show that liability to bone injuries and fractures rose rapidly and did not diminish until 1922 (*Planning*, No 44, Feb 12, 1935) On the other hand, a short time ago, the island of Nauru in the Pacific suffered from a most alarming outbreak of beriberi, especially infantile beriberi the officials in charge of the island had first of all encouraged the consumption of milled cereals, and then forbidden the consumption of the intoxicating national drink—'toddy'—made from fermented sweet swathe of the coco-nut Thus the diet was deficient in vitamin B_1 It is dangerous for authority, with inadequate knowledge of problems of nutrition, to control food policy.

What then is a proper diet ? Much of the teaching of modern research may be summed up in statements so simple that elaborate scientific efforts may, to some minds, seem to have been superfluous. To convey the essentials of to-day's scientific teaching, it is only necessary to insist that fresh green vegetables and fruits are not luxuries but necessities, and that cereal foodstuffs, and especially cereals artificially fractionated, must not so dominate a diet as to exclude an adequate supply of fresh animal products—if not of flesh, then of the products of the dairy In this connexion it may be pointed out that a review of the voluminous literature indicates that pasteurisation of milk, when properly carried out —an important reservation—affects its nutritional value to no more than a negligible degree. Nevertheless, it is a sound policy to encourage the practice of giving extra sources of vitamins A, C and D

Why is the application of these discoveries only slowly taking place ? The issue of *Planning* referred to above points out that, apart from the inherent difficulty of changing ingrained habits of thought and living, there is no general agreement on standards of nutrition and so on what constitutes malnutrition There is an urgent need for a trustworthy standard, based upon objective tests capable of universal and uniform application, so as to yield comparable results in different places and periods

Education of the public in the facts of nutrition as disclosed by modern research is an essential Properly presented, public taste will respond to our increasing knowledge of the factors necessary to make a diet completely adequate , in fact, it has already responded to a remarkable degree, considering the number of obstacles—confusion, inertia, lack of co-ordination and vested interests of all sorts—which stand in the way. Thus, compared with the average of 1924–27, our 1932 *per capita* consumption of margarine fell by 20 8 per cent and of flour by 2 per cent (bread remaining unchanged), while consumption of fruit rose by 8 2 per cent, of milk by 15 5 per cent, of eggs by 32 7 per cent and of butter by 40 3 per cent These changes are not parallel to changes in price . consumption of bread has not increased in spite of the fall in price, and the consumption of milk and eggs has increased considerably faster than prices have fallen

At the same time, it must be emphasised that our knowledge is far from complete. We do not know the optimum intake of calories for children of different ages, or the optimum supply of the individual vitamins We do not know what beneficial modifications of a dietary may be desirable at special periods of life, as at puberty, for example, or in the case of a pregnant woman. These are merely instances of knowledge yet to come. There can be no doubt, however, that a general and intelligent application of existing knowledge would lead to betterment in the health of the nation ; large and delicate readjustments are called for, which will intimately affect social habits and will touch directly or indirectly the development of many industries and branches of distribution.

Reviews

The Carotenoids

Carotinoide: ein biochemischer Bericht uber pflanzenliche und tierische Polyenfarbstoffe Von Prof. Dr. L Zechmeister. (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band 31) Pp xii+338. (Berlin Julius Springer, 1934.) 29.40 gold marks

IN the last decade, perhaps the most rapid progress in any field of organic chemistry has been in that of the natural colouring matters. The anthocyanins have been mastered by Robinson and the porphyrins and chlorophyll by Hans Fischer; but it is the carotenoid pigments which have provided the most sensational progress, mainly in the hands of Karrer and of Kuhn.

Carotene was discovered by Wackenroder in the root of the carrot in 1831, and lycopene in the tomato by Millardet in 1876, though it did not receive this name until 1903, from Schunck Before the beginning of this century the carotenoids were chiefly studied by botanists and physiologists, and though their results were of considerable biological interest, little information on the chemical properties of these substances was obtained. Then Willstätter, at the same time as his researches on chlorophyll, investigated the yellow pigments of the leaf, developing methods for their isolation and purification and establishing for the first time their correct formulæ.

It was a tragedy that Willstätter's work was interrupted by the outbreak of the War, and his skilled collaborators dispersed to their respective countries to take up arms against one another. The work on chlorophyll and the carotenoids was never resumed owing to the cost of the material and of the large amounts of organic solvents necessary. Willstätter had established the empirical formulæ of the chief carotenoids; lycopene and carotene were shown to be isomeric hydrocarbons with forty carbon atoms, and leaf xanthophyll to be a dihydroxy carotene He had also guessed correctly the type of compounds they are, in suggesting for them, as for phytol, the alcoholic component of chlorophyll, the isoprene building stone found in the terpenes and rubber.

So the problem of their structure lay until 1927, when Prof. Zechmeister showed by catalytic hydrogenation that carotene and xanthophyll contained eleven ethylenic linkages and must be bicyclic, while lycopene contained thirteen ethylenic linkages and was an unsaturated aliphatic molecule At the same time, Kuhn and Winterstein had synthesised the important series of diphenyl polyenes, the colour of which depended on a chain of conjugated double bonds. Theoretical qualms about the possibility of a purely aliphatic hydrocarbon being so intensely coloured were at once dispelled, and it became clear to several chemists that the carotenoids owed their colour also to a chain of conjugated double bonds Kuhn and Winterstein applied these ideas to the carotenoid bixin from annatto, while Karrer simultaneously applied them to crocetin from saffron The carotenoids, being built up of isoprene units, are polyene pigments with methyl side chains, or 'polyprenes'

It had long been observed that a smell of violets is produced when carotene autoxidises, and Karrer and Helfenstein brilliantly seized on this clue and proved the odour was due to β-ionone Ionone rings were shown to be the cyclic structures present in carotene, and on the basis of oxidation experiments the correct formulæ for carotene and lycopene were suggested exactly one hundred years after the publication of the discovery of carotene

A feature of these formulæ is their symmetry about the middle of the molecule, one half being the mirror image of the other this was originally suggested by analogy with the triterpene squalene occurring in fish livers, which was synthesised by Karrer and Helfenstein after they had reinterpreted the structural evidence provided by Heilbron, but is now proved absolutely by direct experimental evidence, due chiefly to Kuhn.

This symmetrical structure of the C_{40} carotenoids has suggested to many a relation to phytol, which was synthesised by F G Fischer in 1929, two molecules of which joining together form the essential skeleton of the carotenoids The evidence from plant physiological sources on the relation between the carotenoids and chlorophyll is contradictory, and remains to be satisfactorily interpreted. Phytol is always found in chlorophyll and is never known to be replaced by any other alcohol On the other hand, carotenoids develop in bacteria which contain no chlorophyll It is to be hoped this problem will be attacked again.

Investigation of plants has brought to light three isomeric carotenes and a series of hydroxy carotenes or xanthophylls with one, two, three, four or six hydroxyl groups, the last is the fucoxanthin of brown algæ, and it is likely that new carotenoids remain to be discovered in the algæ In the petals of a flowering plant as many as five different carotenoid pigments may exist together, and it is obvious that they are formed one from the other, though so far this has not been imitated in the laboratory. A particularly interesting but little understood relationship is that of carotene to lycopene; it has been shown, for example, that tomatoes ripened above 30° C. do not produce lycopene.

Besides the C_{40} carotenoids of general distribution, there exist in plants rarer carotenoids with a smaller carbon skeleton, the ascertained structure of which proves without doubt that they are derived by oxidative cleavage of the C_{40} carotenoids In saffron, not only is the pigment crocin known, but also Kuhn and Winterstein were able to isolate the other fragment of the original carotene molecule as the glucosidic bitter principle picro-crocin, an extremely elegant demonstration of the course of biosynthesis

The identification by von Euler and Karrer of carotene as provitamin A, being converted and accumulated in the animal as the almost colourless vitamin A, is a familiar story which need not be repeated here It is the most important result of the study of the carotenoids To chemists the interest is the limitation of the activity to carotenoids in which the β-ionone ring is unsubstituted and its failure in derivatives like the xanthophylls, the physiological importance of which is not yet established A fascinating problem is the source of vitamin A in fish livers, and the discovery of the point in the complicated food cycle on which fish depend at which carotenoid is transformed into vitamin.

To-day the nation is beginning to demand quality in its milk and butter supplies, it is found that the carotene content of butter runs parallel to its vitamin A content, thus serving as an indicator of quality Winter butter contains much less vitamin than summer butter, and so the practice of artificially colouring butter to appeal to the consumer's eye conceals its poor quality. The irony of the practice is evident when it is realised that the substances annatto and saffron used for artificial colouring are themselves carotenoid pigments, but neither of them possesses vitamin A activity!

Some of the plant carotenoids are absorbed by animals and deposited or excreted unchanged, like carotene in the corpus luteum of the cow and xanthophyll in the yolk of eggs; on the other hand, they may be considerably modified; many animal carotenoids require study, as a reference to Palmer's monograph (1922) reveals. An example is the C_{40} carotenoid which is the red pigment of the lobster, before cooking, the lobster has a blue colour due to an absorption complex of this pigment with protein, which dissociates on boiling to give the familiar red. A similar carotenoid-protein complex has been related to the visual purple of the eye according to a NATURE correspondent.

Not the least useful outcome of the activity in carotenoid chemistry is the developments in contemporary chemical technique to which it has led. Microcombustion analysis made carotenoid chemistry possible, but its prosecution has led to the development of microhydrogenation, a method for determination of methyl side chains, and to the rediscovery and popularisation of a new method of purification of chemical substances, 'chromatographic adsorption'.

Prof Zechmeister's monograph is the first to record the chemical knowledge of the carotenoids. It gives an excellent and detailed account of the individual carotenoids, the methods of establishing their structure, their distribution and determination in plants and animals, their relation to vitamin A, and it discusses their formation in the plant and their physiological rôle There is a complete bibliography and a good index. It is to be welcomed as an authoritative work from one who, through his own researches, is well qualified to write on the subject, and whose own contributions to it have been important

K F ARMSTRONG.

Modern Science for the Layman

The Architecture of the Universe By Dr W. F. G. Swann Pp x+428 (New York The Macmillan Co., 1934) 16s. net

MANY are familiar with the lectures on various general aspects of science which Dr. Swann, director of the Bartol Research Foundation of the Franklin Institute, has delivered in recent years. Their publication in the *Journal of the Franklin Institute*, *Science* and elsewhere has secured for them a wider public than that of their original auditors—a fact which, on account of their general excellence, is matter for satisfaction. Dr Swann has now collected them to form a well-produced volume which can unhesitatingly be recommended to all who are interested in the broad significance of modern scientific thought.

The book includes twelve lectures which, though strictly speaking they are independent of one another, are yet arranged so as to present a rough approximation to continuity It corresponds closely, the author tells us, to a course of lectures on the philosophy of physics given at Ohio State University during the summer of 1932 Starting with an account of medieval and modern dogmas in natural philosophy and the dawn of the modern era, it takes us through atomic theory, relativity and problems of space, time and the universe, to a concluding discussion, necessarily more speculative than that which precedes, of vital processes and the relations of science with theology.

It is superfluous to tell those who know Dr. Swann's facility in the popularisation of science that the book is trustworthy and interesting, though occasionally (as, for example, in the two references on p 235 to the star "Krueger" instead

of "Kreuger 60") the author betrays his unequal familiarity with all the subjects treated Such blemishes, however, are few and unimportant If we have a controversy with Dr Swann it is less in his practice than in his theory of popular writing "I cannot escape the belief," he writes in the preface, "that a great deal of the confusion which is frequently left in the mind of the layman after reading a popular presentation of some of the more abstruse branches of natural philosophy, is a result of an unnecessary subjugation of the philosophical and mathematical ideas" This may be so, but is not an unnecessary exaltation of the mathematical ideas a much greater and commoner evil? How many lay students of relativity, for example, have not been completely misled by talk of 'curvature' of space-time, having been induced thereby to search for a mental picture of something similar to the familiar curvature of a sphere? The whole conception is, of course, primarily a mathematical one Its application to the sphere corresponds to the familiar notion of curvature, while its application to space-time corresponds to nothing so imaginable Surely it would have been better if in popular presentation, the 'mathematical idea' had been eliminated and the theory expressed, as it easily can be, in terms of intelligible operations

On the whole, however, Dr Swann's exposition calls for little but praise H D

Experimental Optics

Physical Optics. By Prof Robert W Wood Third edition Pp xvi+846+18 plates (New York. The Macmillan Co, 1934) 31*s* 6*d* net

PROF R W WOOD'S "Physical Optics" was issued in 1905 and revised in 1911, when it was expanded by 150 pages, with nearly a hundred new illustrations. The new edition shows a similar expansion of 132 pages, but includes nearly 500 pages of new material, nine new plates, and more than 150 new illustrations The photographs thus reproduced were, however, designed for use rather than for ornament, and are disappointing in comparison with the beautiful pictures which are often used to illustrate spectroscopic phenomena

The book retains its unique character as a record of experimental methods and results, and is of special value as a guide to the contributions to physical optics which have been made in the laboratory of the author at Baltimore It is difficult to realise that the second edition goes back to a date preceding the development of Bohr's theory of line spectra Quantum theory was then covered by a couple of pages on the "very recent light-quanta hypothesis of Planck and Einstein", and the remainder of the book was based exclusively upon 'classical' methods of analysis The new edition therefore provided an opportunity for writing up *de novo* the whole of the work done in applying the quantum theory to optical phenomena In the hands of so keen an experimenter as Prof Wood, the narrative takes on an unusual form, since it is founded on observation and consequent theory rather than conversely The new chapter on "The Origin of Spectra" is therefore exceptionally well-adapted for readers who think more easily in terms of facts than of symbols, and the same features are seen in new chapters on resonance radiation and fluorescence of atoms and molecules, and in the reconstructed chapters on magneto- and electro-optics, in the course of which the spinning electron is introduced as a solution of the problem presented by the 'abnormal' Zeeman effect in light emitted in a magnetic field

In his original preface, the author expressed the hope "that the perhaps too frequent references to experiments with which he has been more or less directly associated will not be taken as an indication of a lack of perspective" In view of this frank acknowledgment, the reader need not be unduly disappointed when he finds that other topics are dealt with much less adequately Thus, in the new edition, refractive dispersion in the region of absorption is still discussed in terms of 'damping', and the sections dealing with absorption are equally inadequate, since a well-qualified colleague has remarked that the author's commendation of Vierordt's spectrophotometer, which "would now be considered a museum specimen", is "about sixty years out of date" Similarly, in a field in which the reviewer is specially interested, an erroneous statement that the anomalous rotatory dispersion of tartaric acid depends on an optically active absorption band in the infra-red, has been deleted, but no new data have been added, and half a dozen measurements, made in 1858 by methods which have been obsolete for more than half a century, are still cited as adequate illustrations of this phenomenon. In this chapter, moreover, the author has abandoned his policy of describing facts rather than theories, since the only important addition is a summary of Werner Kuhn's theory of dissymmetrically coupled electrons, which is already becoming obsolescent in view of more recent work by Born Readers who wish to learn about modern work in branches of physical optics not of special interest to the author must therefore be prepared to seek information elsewhere, but others will be equally grateful to him for leaving these alien topics to take care of themselves, in order to concentrate on those questions about which he can give so much interesting first-hand information T. M LOWRY

Short Notices

Science Museum, South Kensington. *Handbook of the Collections illustrating Electrical Engineering.* 2 *Radio Communication* By W. T O'Dea Part 1 *History and Development* Pp 95+35 plates (London H M Stationery Office, 1934) 2s 6d net

THE objects of the Science Museum at South Kensington, with its collections and science library, are to assist in the study of scientific and technical development, and to illustrate the applications of physical science to technical industry For the guidance of students and others visiting the Museum, a series of handbooks is in existence, illustrating the various collections exhibited. The book under review is one of those dealing with the electrical engineering collections It is, however, by no means a mere descriptive catalogue of what may be seen at the Museum It is rather a concise and well-presented history of the development of radio communication from the earliest discoveries of Hertzian waves up to the present-day achievements of telegraphy, telephony, broadcasting and television

The value of the work is considerably enhanced by the large number of photographs which illustrate the progress made in the plant and apparatus used for radio communication purposes Many of these items are quite obsolete, and the preservation of a knowledge of them, partly by exhibits in the Museum and partly by the illustrations in this work, is a valuable undertaking Of the few points in the book which call for criticism, one will be mentioned here Insufficient recognition appears to have been given to the very valuable technical work carried out during recent years by members of the staff of the British Post Office, which has been very largely responsible for the development of radio-telephonic communication to its present world-wide standard

Although technicalities have been reduced to the minimum, some knowledge of the technique of the subject is desirable on the part of the reader To the student, in particular, the book will provide a valuable historical supplement to his more detailed textbooks

Soil Analysis a Handbook of Physical and Chemical Methods. By C Harold Wright. Pp viii+236 (London : Thomas Murby and Co ; New York : D. Van Nostrand Co , Inc , 1934) 12s. 6d net.

THE number of analyses conducted every day on soils must be very large, yet apart from Gedroiz's and Lemmermann's works in Russian or German, and Wiley's "Agricultural Analysis", vol 1, there was until now no textbook on the subject. Most workers have had to get their information from sections in general textbooks or in the "Chemists' Year-Book", or from the original literature In the inevitable phrase, then, Wright's "Soil Analysis" supplies a long-felt want Moreover, it does so exceedingly well. Without being cumbrous, it is comprehensive ; and—a matter of particular importance in a subject where methods are revised and new conceptions are introduced as rapidly as in soil science—it is right up to date

There is a full array of chemical determinations, including those, such as ammonia and nitrate, useful to the microbiologist In addition, the book describes methods of determining physical constants, and making physico-chemical measurements, paying particular attention to soil reaction and base exchange. In footnotes and in tables of factors the author brings his own experience to the aid of workers who may be using a method for the first time The number of illustrations might usefully have been increased, but the book is well produced and commendably free from errors

Textbook of Abnormal Psychology By Roy M Dorcus and Prof G Wilson Shaffer Pp xiii+389 (London · George Allen and Unwin, Ltd , 1934) 16s net.

THIS is a most instructive and valuable work It is written by two psychologists who bring to their work a critical faculty and logical training that one does not always find in books dealing with abnormal, or for that matter normal, psychology.

When viewed from a medical point of view, however, there is a superficiality and vagueness which leaves a feeling of uneasiness The statement that . "Swingle and Pfiffner . have discovered an aqueous extract of the adrenal cortex which has proved astonishingly valuable in the treatment of cats " may sound thrilling, but what *were* the cats suffering from ? We would have liked to see some discussion of the relationship between the adrenal glands and emotion.

The writers might have emphasised that in true paranoia there is an absence of hallucinations, and that mental deterioration does not occur. The adjective corresponding to paranoia is paranoiac, not paranoid. Despite shortcomings which can all be corrected in the next edition, the book is on the right lines, and we welcome it.

Soviet Russia fights Neurosis. By Dr. Frankwood E Williams. Pp. xix+251. (London . George Routledge and Sons, Ltd , 1934) 8s. 6d not.

DR. FRANKWOOD WILLIAMS went to the U S S R. as a psychiatrist to see for himself the state of affairs. He found many strange and inexplicable conditions and views. Possibly the position is best summed up in the reply to a criticism of his , instead of answering the criticism the reply was evasive and turned at once to 'Yes, but have you seen the museum of the Revolution, the park of Culture and rest, a factory, a public kitchen ?' The planning is all there but the execution is another matter ; the Russian citizen seems to blind himself to those things he does not wish to see Is not the U S S.R. suffering from a mass obsessional neurosis ?

Respiration of Fruits*

MECHANISM OF RESPIRATION

DURING respiration, the entrance of oxygen and its distribution through the tissues to the individual cells of a fruit, also the reverse processes involving the giving off of carbon dioxide, take place by diffusion There is a fine network of channels ramifying through the tissues to aid such gaseous interchange The diameter of the pulp cells of the full-grown apple is about 150μ, and of the channels about 5μ. The surface of interchange is very large, being a square metre for a single fruit The intercellular space is 10–20 per cent of the whole tissue In such a system as this, there must be gradients of gaseous concentration, though it can be shown that such gradients are very small

The peel of the apple plays an important part in regulating gaseous interchange between the fruit tissues and the atmosphere The cells of the peel are smaller and more compact than those of the parenchyma beneath, and their outer walls are covered with a thick cuticle which is comparatively impermeable to gases But the peel is broken by a system of pores, which constitute a path of gaseous interchange. That the peel constitutes a resistance to the path of gaseous interchange can be shown by setting up two apples with 100 per cent atmospheres of carbon dioxide at their centres, one apple with the skin removed and the other with the skin intact The escape of carbon dioxide observed will be much greater in the former. Owing to the resistance to diffusion offered by the peel, the composition of the internal atmosphere differs considerably from that of air Conditions can easily arise which lead, through a conjunction of low skin porosity and high respiratory activity, to concentrations of carbon dioxide inside the fruit which are directly injurious So much has been definitely shown, but so far no thorough study of the internal atmosphere in relation to the variables affecting it during growth and storage has been carried out.

CHANGES IN RESPIRATORY ACTIVITY

Throughout its life-history, the apple shows distinct changes in respiratory activity These may be correlated with the five morphological and physiological stages which occur during the development of this fruit. First, there is the stage of *cell division* which lasts from fertilisation until about three or four weeks afterwards, when the fruit is about the size of a walnut. This goes on until about a hundred million cells are formed in a typical fruit, after which the number of cells does not appreciably increase The *enlargement* of these cells constitutes the second stage Then the fruit *matures* and produces aroma and flavour This is the third stage Now the fruit is ripe, and under natural conditions it falls from the tree The fourth stage follows as a longer or shorter period of *senescence* The fifth stage is the functional breakdown culminating in *death*

Respiratory activity is greatest at the beginning of fruit formation, at the end of cell division (first stage) it has fallen to about one fifth of its original value During cell enlargement (second stage), respiration continues slowly to decrease During the process of maturation (third stage), a critical change in respiratory activity occurs in that there is a sharp rise This may be called the *climacteric* Senescence (fourth stage) sees a slow decline from the peak of respiratory activity reached during the climacteric Finally, at death (fifth stage) there is a sudden rise followed by a fall to zero.

CHEMISTRY OF RESPIRATION

The most important substances connected chemically with the respiration of the apple fruit are sugars (fructose, glucose and sucrose), acids (mainly malic acid), starch and proteins

During the first stage, the proteins are the chief constituent of the practically non-vacuolate cells During cell enlargement, sugars accumulate from about 1 per cent to about 9 per cent fresh weight Vacuoles appear and occupy about 80 per cent of the cell volume In these, most of the sugars collect It is significant that fructose and sucrose are the sugars the concentration of which rises, while glucose remains relatively low and steady in concentration Starch accumulates in the cytoplasm up to about the middle of this stage, after which it diminishes to zero

Tissue oxidations are associated with enzyme catalysis, determined by (1) enzyme content and (2) content of respirable material So, to be more exact, the standard of reference should not be unit fresh weight as heretofore used, but unit *living matter*, thus omitting vacuole and cell wall. Considered thus, the fall during the first period is smaller and may be related to a decrease in enzyme activity In the second stage an increase in respiration occurs, due to the accumulation of the necessary fuel sugars.

If fruit is gathered during the second stage of growth, respiration rapidly falls Then there is a pause, followed by a continuation of the decrease The respiratory activity then settles to a steady

* Substance of the Friday evening discourse delivered by Dr Franklin Kidd at the Royal Institution on November 9, 1934

decline This is followed in due course by the climacteric rise, the senescent decline, and the final burst of activity falling away to zero (Fig 1)

The chemical changes in fruit gathered at this stage and stored are as follows As soon as the fruit is gathered, the starch content declines and glucose content naturally rises But, surprisingly, fructose, and sucrose also, rise The end of the pause in initial fall of respiratory activity marks the final disappearance of starch

As soon as starch is no longer present, the sucrose begins to disappear, the total fructose content remaining steady, while the total glucose content falls Unlike starch, however, sucrose does not completely disappear These changes are considered to complete the phase of adjustment to starvation conditions (Fig 2)

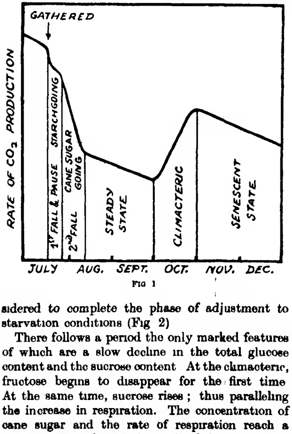

FIG 1

There follows a period the only marked features of which are a slow decline in the total glucose content and the sucrose content At the climacteric, fructose begins to disappear for the first time At the same time, sucrose rises ; thus paralleling the increase in respiration. The concentration of cane sugar and the rate of respiration reach a maximum together at the peak of the climacteric and thereafter decline together

In explanation of these changes, the heterogeneity of the cell system and the probability that respired sugars are not equally distributed must be taken into account and also the fact that, after gathering, the cells are changing from a state of growth, and of supply and accumulation, to one of cessation of growth and of supplies. The theory advanced is that the sugar respired is active or γ-fructose. Other things being equal, the rate of respiration is determined by the concentration of this active sugar in the cytoplasm The principal reactions determining concentration of active fructose are

(I) Glucose $\rightleftarrows$ active fructose $\rightarrow$ inactive fructose or other normal hexose (vacuole)

(II) Glucose + active fructose $\rightleftarrows$ sucrose (vacuole), and the seat of these reactions is thought to be at the interface between the cytoplasm and the vacuole It is further suggested that prior to the climacteric, sucrose and normal fructose do not as such penetrate from the vacuole into the cytoplasm. When the fruit is on the tree, glucose arrives at the cell wall and passes across the cytoplasm through a declining diffusion gradient. At certain points in the cytoplasm any excess of glucose above a certain concentration is condensed to starch At the interface between cytoplasm and vacuole the conversion of some of the glucose into active or γ-fructose takes place, and the formation of cane sugar occurs

The theory accounts for the accumulation of sucrose and fructose in the vacuole during growth and supplies an answer to the questions Why, after gathering, are the cells unable to maintain a high concentration of cane sugar ? Why, nevertheless, does the concentration of cane sugar rise after gathering so long as starch is present ? Why, finally, does a steady low concentration of cane sugar occur instead of a complete disappearance as in the case of starch ?

With the onset of the climacteric, it is supposed that the interface between vacuole and cytoplasm becomes permeable to normal fructose This change in permeability is connected with the inner surface of the cytoplasm and possibly with the attainment of a critical hydrogen ion concentration in the vacuole The acidity of the vacuole is due to the organic acid present Whether the apple remains on the tree or is gathered, the acidity of the vacuole steadily falls from the beginning of the cell enlargement stage at approximately the same rate. This explains why the climacteric rise occurs very nearly at the same time, irrespective of date of gathering, since the acidity falls in any case, at about the same time, to a certain critical level at which the climacteric occurs. Other evidence has been obtained that the acidity of the vacuole is the main factor in determining the onset of the climacteric.

STORAGE OF FRUITS

The climacteric marks the beginning of the production of odour and flavour. Experiment has shown that a substance is evolved during this stage—a substance toxic to seeds and destroyed by bromine. This substance is produced in such small quantities that its identification is not easy ; but there are reasons for believing that it is the gas ethylene. The biological effects of the vapour

from ripe apples and of ethylene on other plants are the same Both, for example, cause an immediate rise in the respiratory activity of other unripe fruit, and this rise bears every resemblance to the true climacteric rise of ripening Thus unripe fruits exposed to the vapour of ripe fruits begin ripening at once Such 'autocatalysis' can be prevented by treating air passing from the ripe fruit with ozone

Among other substances produced at the climacteric is a dense, slowly diffusing vapour which causes the browning of the skin of the apple Such deterioration can be avoided by very rapid ventilation with fresh air A more practical way, however, is to wrap the apple, *during the climacteric*, in tissue paper impregnated with an odourless mineral oil

The production of such gases during the climacteric is also responsible for increased susceptibility in apples to low temperature injury when kept in cold storage. How far the origin of these toxic substances can be traced to fructose is not yet known

INTERMEDIATE STAGES OF RESPIRATION

Fruit can produce carbon dioxide in the absence of oxygen by respiration Blackman and Parija have shown that the initial rate of such fermentative breakdown in a ripe apple is a function of the oxygen supply prior to its removal to anaerobic conditions (nitrogen atmosphere) They therefore concluded that the first stages of sugar breakdown are anaerobic in any case, and that oxygen has a stimulating effect on the supply of this sugar But this theory, though it explains the decline in respiration after removal of the fruit to anaerobic conditions, does not explain why such decline is *not to zero* but to a constant level of activity Thus, although oxygen stimulates supply of respiratory sugar, it is not essential to it

Trout, realising that acetaldehyde is given off by ripe apples, and that this substance is also a recognised intermediate product during the fermentation of sugars, examined the effect of supplying acetaldehyde artificially to fruits When supplied slowly, the added aldehyde quickly became oxidised. On the other hand, when supplied quickly there was a definite rise in aldehyde content and at the same time ethyl alcohol appeared in the tissues The two processes of oxidative and fermentative breakdown appeared to be proceeding together with a consequent increase in rate of sugar loss. From this, Trout suggested that the fermentative process takes place as far as the acetaldehyde stage irrespective of oxygen present. After that, if much oxygen be present, the aldehyde is oxidised to carbon dioxide and water, or, on the other hand, if no oxygen is present, it reacts with methyl glyoxal, formed in the first splitting of the sugar The former process must be the more rapid one, and therefore in the presence of oxygen the concentration of aldehyde in the tissues is low When it is artificially raised, the reaction with methyl glyoxal occurs and the results obtained are to be expected If this hypothesis be correct, glycerol must be formed, but, since it is known not to accumulate, we must assume, following the Blackman theory of oxygen-anabolism, that glycerol is the substance which is re-synthesised to sugar

Experimental evidence suggests that the removal of oxygen from apples in the post-climacteric state is the elimination of the factor which produces the

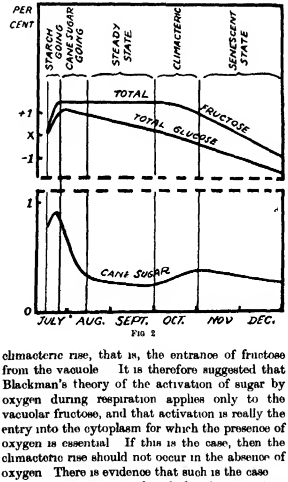

FIG 2

climacteric rise, that is, the entrance of fructose from the vacuole It is therefore suggested that Blackman's theory of the activation of sugar by oxygen during respiration applies only to the vacuolar fructose, and that activation is really the entry into the cytoplasm for which the presence of oxygen is essential If this is the case, then the climacteric rise should not occur in the absence of oxygen There is evidence that such is the case

During senescence, a slow decline in respiration occurs. Aldehyde and alcohol increase during this period, and it is suggested that this is due to diminishing activity of the system for the oxidation of aldehyde by molecular oxygen Indeed, ageing apples become increasingly sensitive to lack of oxygen Quite a small decrease in amount of oxygen in the atmosphere causes fermentation in apples which are in an advanced state of senescence.

Respiration and Life Duration

Fruits of a short life-cycle, such as the strawberry, exhibit a higher respiratory activity than fruits of a longer life-cycle such as the apple. Variation occurs, however, even within a species For example, in apples, the variety Bramley's Seedling respires at about two-thirds the rate of the Worcester Pearmain The life duration of the latter is about one and a half times that of the former Respiratory activity also varies with the nutrition of the fruit during growth Therefore, if respiratory activity during cultivation of the fruit be increased by increasing the nitrogen content of the soil, life during storage is shortened, and vice versa A more striking example, however, is the result obtained by gathering fruits at various stages during the second period of growth. At the beginning of this period, the cytoplasm and the cane sugar per cell are at their minimum, and so therefore is respiratory activity Fruit gathered at this stage will thus have a longer life during storage than fruit gathered at any subsequent stage

A young apple, in spite of the fact that it contains little carbohydrate when gathered, loses more carbon before death than does a full-grown fruit A full-grown fruit does not usually lose more than 0 2–0·4 per cent of its carbohydrate and acid prior to death. It appears likely that it is the 'rate of living' which kills and that the machine breaks down from wear and tear and not from lack of fuel

From these observations, three new agencies have come into use for the purpose of controlling the span and speed of life in fruits, namely: (1) use of ethylene as an accelerator of ripening, (2) use of carbon dioxide as a depressor of respiratory activity, thus retarding ripening and lengthening life, (3) the use of atmospheres poor in oxygen, thus reducing respiratory activity, delaying the climacteric and retarding ripening

The possible use of ozone in controlling ripening is still in the experimental stage

The Teaching of Optics*

OPTICS and mechanics are twin Cinderellas in the teaching of elementary physics The beginner finds with growing disappointment that each covers ground remote from those thrilling matters of real life that they promised to deal with—remote from engines and machinery and from real optical instruments such as telescopes and microscopes To make matters worse, a confusing fight rages round the teaching of each . a battle of units in mechanics, in which the mass and the weight of the projectiles employed seem inextricably mixed, and a battle of signs in optics, with $1/v-1/u=1/f$ and $1/v+1/u=1/f$ as its war cries Mechanics has been rescued by the toy manufacturers—if we may call admirable constructional apparatus such as 'Meccano' toys—and the mathematical studies of mechanics which seem so artificial if attacked too early are left until the later school stages when they can bring a real delight unspoiled by disappointed hopes of romance.

Optics may follow a similar path with constructional sets of lenses and mirrors as Christmas toys to provide the practical delights that formal teaching often misses ; and for several years such sets have been on sale, with optical components and adjustable framework for making a variety of working optical instruments. We grudge no toyshop such excellent wares, yet we cannot help feeling that elementary optical teaching is at fault and should itself capture and use some of the thrills that belong to actual instruments, before attempting to build a formal structure—an attempt long ago condemned in other branches of teaching Many teachers, feeling this, now begin optics with a course that is not merely simplified but wholly changed in order and emphasis, yet even they must feel the drag of examination demands, textbook styles and the weight of tradition So it is pleasing indeed to find that the Physical Society's Report urges that "The early approach to lens and mirror optics is best made along experimental lines, and every effort should be made to implant a sound conception of the main physical phenomena of image formation before mathematical formulæ are introduced", and suggests that an *experimental* start, free from mathematics, might be made with, "for example, elementary illumination and photometry, and the action of simple instruments such as the telescope, microscope and projection lantern". The Report says regretfully, "In only too many cases the beginning and end of optical instruction in schools seems to be bound up with $1/v - 1/u = 1/f$", a type of formula which, as one of the authors says later in the Report, is not much used in real optical work !

While the Report expresses these hopes for the future of elementary teaching, its main concern is with the conventions of signs in optical formulæ.

* Report of the Committee appointed by the Physical Society to consider and make Recommendations on the Teaching of Geometrical Optics. Pp v+86 (London Physical Society, 1934) 6s net.

At present six or more different conventions are in use in textbooks in English Most teachers, and presumably all examiners, must wish that some competent authority would choose one convention and enforce its universal use But each wishes the chosen rule to be the one he uses himself, so the only chance of effecting a successful choice is for the pronouncement to come from a body of such high authority as to compel the agreement of teachers, examiners and authors alike This Report gives just such a pronouncement It is the result of five years work by a distinguished committee which included representatives of a wide range of optical and educational interests It carries such a weight of authority that its recommendations, though they can only be made as suggestions, ought to be accepted as law

The Report considers the current conventions of sign relating to formulæ such as $1/v \pm 1/u = 1/f$ From the half-dozen actually in use the Committee chooses two—the members themselves were unwilling to reduce their choice to one Reasons are given for this preference, and it is urged that one of these two should be adopted in future in elementary optical teaching, and so far as possible, in advanced teaching The Committee is unanimous in recommending that teachers in schools and universities should be asked to employ the practical opticians' convention which gives a positive power to a 'converging' lens, negative to a 'diverging' one As most school teaching at present uses the opposite convention, neither of the two general sign conventions recommended is in use in any school textbook, but both are as good and clear and easily grasped as those now in use So in schools the recommended changes will be slightly unwelcome to all at first, but ultimately very welcome

The recommendations include the following

(1) Converging lenses should be assigned positive power; diverging negative Focal lengths should have the same signs as powers, as far as possible

(2) That 'power' (equal in elementary cases, in air, to $1/(f$ in metres)) should be used in preference to focal length, where convenient

(3) That an instrument (without erecting mirrors or prisms) should be assigned positive power if it produces an inverted image of an infinitely distant object; negative if the image is erect.

(4) That the numerical value of the power of a system be measured by the small angle subtended by an infinitely distant object divided by the length of its image. (A corresponding definition gives the focal length, and the Report suggests that this be made the basis of a laboratory method for estimating—but most school laboratories lack the space and the measuring microscopes necessary for accurate use of this method.)

(5) That in more advanced work when refractive indices are inserted, all formulæ should be made homogeneous in μ or μ' For mirrors we should write $\mu/v + \mu/u =$ power, and power $= \pm 2\mu/r$.

(6) That the convention of signs be changed, in the course of time, to either of two recommended rules, described below as Group I (i) and Group II (i)

GROUP I (i) Distances measured from the lens or mirror are assigned *positive* values when measured in the *same* direction as the incident light and *negative* values when measured in the *opposite* direction For example, if a lens placed 20 cm from a real object forms a virtual image 30 cm on the other side, then $u = -20$ and $v = +30$ To obtain the signs for power required by the convention mentioned in (1) above, we must use $1/v - 1/u = 1/f$ for a lens, and $1/v + 1/u = 2/r$ for a mirror.

GROUP II (i) Distances are measured *along a ray* (instead of along the axis; but this makes little numerical difference in elementary practice and need not complicate the teaching) and are assigned *positive* or *negative* values according as the object or image to which they relate is *real* or *virtual* Distances are positive if light has travelled along them and negative if it only appears to have done so. Thus u has a positive value if the object is real and v has a positive value if the image is real, wherever it is This convention emphasises the distinction between the image space of, say, a lens, and the object space Each space extends on *both* sides of the lens, having positive distances on one side and negative on the other For a lens the positive portions of object space and of image space are on opposite sides, for a mirror on the same side For example, if a lens placed 20 cm from a real object forms a real image 30 cm on the other side, then $u = +20$ and $v = +30$. We must use $1/v + 1/u = 1/f$ for a lens and the same formula for a mirror

Both conventions apply equally to wave, ray or other treatments Both provide criteria for the signs of angles, magnification, etc I (i) requires only a change of sign from the form common in school teaching, but II (i) promises certain extra attractions, since it uses the same formula for lenses and mirrors, seems to be able to carry a beginner through the thick and thin of an optical system at least as easily as I (i), welcomes the beginner's wish to call both u and v positive when he first experiments with a lens forming real images, and even allows him to forget which is which On the other hand, II (i) requires a re-writing of texts, and some students may not find it so easy in advanced work

We feel that the change to at least some measure of uniformity in optical teaching must be made—school teaching and the whole of commercial and ophthalmic practice cannot both have their own way unless the present diversity is to continue—and these recommendations provide the chance to make it They deserve the support of all future textbooks, and even, so far as possible, advanced treatises The revising of existing textbooks to conform with them would give trouble to publishers rather than to authors Every publisher of scientific textbooks should keep a copy of the

Report, for the benefit of authors as regards new textbooks, and for his own benefit, as regards reprinting existing books Examining bodies could help by expressing, with increasing firmness, their preference for the new conventions But the real demand for willing help must fall on the teacher, and we hope that all concerned with the teaching of elementary optics will be willing to welcome the change when the opportunity for it reaches them, and even, if they feel they can, to initiate it themselves meanwhile All such teachers should examine this Report At first glance it seems to sweep with dismaying rapidity through a mathematical optics that is quite beyond a school syllabus, but on careful reading it shows its authority and its value even for the most elementary teaching The appendixes should be read together, and not taken as restricted each to its own convention Each develops methods and proofs applicable with any convention. The examples seem rather ill-chosen for illustrating the use of signs in elementary work, but on closer examination do reveal the working of the rules, and as solved independently by two experts they are really entertaining.

The Committee does not wish to restrict the liberty of the teacher as regards methods of approach and treatment of the subject The only restrictions it wishes to impose are concerned with routine matters such as conventions of sign There has been ample opportunity for discussion of rival conventions, and now that a pronouncement has been made it is to be hoped that in the course of time all will comply with these recommendations Not to do so would seem to be to deny the readiness of scientific workers to accept a simplification of unnecessarily complicated affairs E M R

Obituary

DR MICHAEL GRABHAM

IN the death on January 28 of Dr Michael Grabham at the great age of ninety-five years, the island of Madeira has lost its most influential personality and the world an enthusiastic naturalist. Dr Grabham, who was educated at King's College, London, and the University of London, qualified in 1861 at St Thomas's Hospital and served there as house surgeon He married Mary Blandy, one of the well-known family of merchant shippers, in 1865, and took up permanent residence as a practitioner on the island of Madeira In that favoured island he produced a book dealing with its every aspect—natural and sociological—a treatise that is still of outstanding value despite the changing times

Dr Grabham usually paid a flying visit to his home country every summer, where he was recognised by many distinguished bodies He received the degrees of M D and LL D. from the University of Aberdeen, F R C P from the Royal College of Physicians, which he represented at the Geological Society's centenary meeting in 1907. In 1921 he delivered the Bradshaw lecture before the College He delivered discourses at the Royal Institution and read papers on the climate and natural history of Madeira before the British Association, of which a few years ago he became the senior member His last paper before the latter body was read in his eighty-eighth year and dealt with the subtropical deep sea food fishes of Madeira.

The Zoological Society of London some years ago established a collecting station in Madeira and to-day can show an unrivalled series of 'Madeira tanks' in its aquarium, each displaying some aspect of the wonderful fauna which exists in the island's coastal waters. For this exhibition Dr. Grabham is partly responsible, since he was first to suggest making Madeira a base of operations Dr Grabham, although not a professional marine biologist himself, was an enthusiastic aider and abettor of all who made marine biology their peculiar interest

Among Dr Grabham's numerous activities were music and the collection of clocks In the former art he proved himself specially gifted, and when visiting London had on more than one occasion the privilege of giving organ recitals in St Paul's Cathedral His collection of chiming clocks numbered more than two hundred, and the writer well remembers his sensations on first spending a night at his host's home at Quinta do Val, when the numerous timepieces solemnly announced the midnight hour for fully sixty minutes before and after Greenwich had agreed with his own watch as to the precise moment of that event

Dr Grabham leaves two sons and one daughter, one of the former, Mr Walter Grabham, being the Government geologist in the Sudan, his daughter, Mrs. E. B Carter, has her own home in Madeira at Santa Cruz, where she spends her holidays and supervises the collecting operations on behalf of the Zoological Society

Dr. Grabham had many friends, and the loss of his charming and energetic personality will be deeply felt by a large circle of friends both in Great Britain and in his island home E G BOULENGER

MR HERBERT G PONTING

THE death of Herbert G Ponting on February 8, at the age of sixty-four years, removes from us perhaps the greatest of all polar photographers, a pioneer in the application of artistic photography to the purpose of a scientific expedition.

The early part of Ponting's life was spent in a diversity of occupations; and he took to photography from the unusual atmosphere of agriculture and mining in the western United States. He rapidly made a name for himself by his pictures in Japan

and China, and he was already well known in photographic circles when, at the age of forty years, he joined Capt Scott's last expedition Here he mixed, possibly for the first time, with a number of men of science who, aware of his reputation, besieged him with special work on their behalf His reaction to these requests was typical of the man His kindness of heart would urge him to take exactly what was required of him, though his artistic sense would rebel against banal subjects that he was set to record Nevertheless, he would take hours endeavouring to make a real picture from such unpromising material as a cliff face or stratification in a glacier

Ponting always maintained that he was not a photographer but a camera artist, and this was truer of him than it could be of most who claim the latter name He was a merciless critic of his own work, and would destroy all negatives which did not come up to the high standard he set himself The noise of breaking glass in his dark room was not uncommon, and usually heralded his reappearance, laden with cameras once more, to go and take his subject over again His cinematograph work was at that time in advance of that done by any previous film traveller The world has only seen a small fraction of the footage taken by him, and he probably spent more actual time with his cinema than with his still camera Here again, however, his work could not be called scientific in the purest sense, largely because the artist in him quarrelled with the man of science, and usually won

Although Ponting was devoted to his work, and had few interests outside it, he recognised its commercial value, and this brought him into touch with the financiers of the film world, a milieu unsuited to his temperament and one in which his experience was not always happy On visiting him at his London flat, one was sure to find him either in the depths of despair at some plans gone awry or full of enthusiasm at some new venture, usually connected with the exhibition of the Scott films

Ponting had a simple and generous mind and he suffered very deeply at the loss of Scott and Wilson He devoted himself for many years to the task of perpetuating their memory through his still pictures and his films. Those who have enjoyed them will acknowledge his success, and many of his camera studies will endure for all time as perfect examples of his art

PROF. O D. CHWOLSON

PROF O. D. CHWOLSON, of the University of Leningrad, who died on May 11, 1934, is well known as the author of a textbook of physics, originally published in Russian and later translated into German, French and Spanish It was one of the first textbooks written for high school students and enjoys a deservedly high reputation. Its success has been due to the masterful treatment of the subjects by a highly gifted lecturer and teacher The first four volumes were written by Prof. Chwolson himself; the last volume consists of chapters written at Prof. Chwolson's request, and on the lines he indicated, by specialists, his pupils, in various branches of modern physics

Prof O D Chwolson was born in 1852 as a son of a well known Hebrew scholar He matriculated at the age of seventeen and took up his studies at the University of St Petersburg He graduated with honours in 1873 The next year he spent in research at Leipzig, but in 1875 he was back again in Russia He took his 'master's' degree in 1876 and his doctorate in 1880 His early research work dealt with various questions of electricity and magnetism, as well as with actinometry The work on actinometry was preceded by some investigations on the mathematical theory of conduction of heat, and the result was an actinometer which for a long time served as a standard type instrument in Russian meteorological observatories

After 1876 all Prof Chwolson's work was devoted to teaching, and among the numerous students of fifty years, there was scarcely one who was not fascinated by his lectures He knew how to address the beginners as well as advanced students, his lectures being carefully prepared

Prof Chwolson took an active part in the teaching of physics in secondary schools and especially in the training of teachers In 1907, he organised a committee for the investigation of the provision for physical laboratories and demonstration rooms in secondary schools, and in 1913, a meeting of teachers in physics, chemistry and geophysics in secondary schools He was elected permanent honorary president of the section of teaching of the Russian Physical and Chemical Society

The great gift of popularisation of scientific achievements added considerably to Prof Chwolson's activities Most of his lectures were afterwards published and make very pleasant reading His books appeal to the average man just as well as to the scientific worker Only a few years ago Prof Chwolson published a book on Modern Physics", dealing with the latest achievements in physics Some 300,000 copies were published, so great was the demand for it in the U S S R

It is scarcely possible in a brief obituary notice to give an appreciation of Chwolson the man, modest, hard working and with true enthusiasm for scientific knowledge The world has benefited from his philosophical conceptions and from his ideas about the influence of science on social life Several generations of physicists, not only in the U S S R but also in other countries, will keep his name in grateful remembrance

WE regret to announce the following deaths

Dr James Clark, emeritus rector of Kilmarnock Academy and formerly principal of the Central Technical Schools for Cornwall, Truro, on February 19

Dr Axel Wallén, director of the State Meteorological Hydrographic Institute of Sweden and president of the Meteorology Association of the International Union of Geodesy and Geophysics, on February 23

News and Views

Lord Bledisloe and New Zealand

ON many occasions since Lord Bledisloe became Governor General of New Zealand in 1930, we have referred to stimulating addresses delivered by him on applications of scientific knowledge to agricultural and other industries, and to economic and social problems In all his addresses, the great importance of research has been emphasised and the results of investigations carried out in Great Britain and in other parts of the world have been brought before the people of the Dominion This has been particularly the case with agriculture, on which subject Lord Bledisloe is himself a high authority It is gratifying, therefore, to learn from a message from the Wellington (N Z) correspondent of *The Times*, that more than 54,000 dairy-farmers have subscribed to an address from their industry recording his thorough understanding of their problems and his assistance in solving them Scientific societies and the newspaper Press in the Dominion have similarly expressed grateful appreciation of his wise counsel and practical guidance

Lord Rutherford's Portrait for New Zealand

DURING his term of office, which closes on March 15, Lord Bledisloe has lost no opportunity of emphasising the important part which science has played, and must continue to play, in the development of the country The most distinguished scientific worker which New Zealand has produced is unquestionably Lord Rutherford, whose name will always be associated with the advance of atomic physics, and Lord Bledisloe proposes to mark the conclusion of his five years of office by presenting to the Dominion a portrait of Lord Rutherford, to be hung in the new National Art Gallery at Wellington By a fortunate coincidence, a distinguished portrait painter who is also a New Zealander, Mr Oswald Birley, was available for the task Mr Birley painted a portrait of Lord Rutherford which was presented to the Royal Institution by fellows of the Royal Society some three years ago Lord Bledisloe therefore commissioned Mr. Birley to paint a replica, which has been sent to New Zealand The presentation will be made at a civic reception to Lord and Lady Bledisloe to be held in the Town Hall, Wellington, on the eve of their departure for England By this public-spirited action, Lord Bledisloe has given New Zealand a striking picture, by one of her own artists, of a son who has achieved an international reputation in the field of science

Death of Lady Dewar

THE death on January 7 of Lady Dewar, widow of Sir James Dewar, was reported to the members of the Royal Institution at a recent general meeting Lady Dewar's long and intimate association with the Institution began in 1887 when her husband, already the Fullerian professor of chemistry, succeeded Tyndall as superintendent of the House. From that time until Sir James Dewar's death in 1923, she was the hostess of the Institution, and the regard in which her memory is held by a wide circle of members and friends is expressed in the words of Sir William Bragg at the general meeting Sir William said that her death "had broken a precious link connecting the present times with those of the past in which Sir James Dewar had made the Royal Institution such a powerful agent of research and exposition Not only had Lady Dewar been the true helper of Sir James in his work she had, as many would gratefully remember, been a most able and kindly hostess to the scientists and others who flocked to see her husband and the Institution over which he presided The members of the Institution would gladly acknowledge their debt to Lady Dewar, and for ever keep her name in appreciation and affectionate remembrance "

Lady Dewar's Bequests for Science

A BEQUEST by the late Lady Dewar is announced of ten thousand pounds to the Royal Institution The gift is free of duty, and is made on the condition that the income is to be used for the purpose of furthering scientific research in the Institution and as a permanent memorial to the work there of her husband, Sir James Dewar Lady Dewar has also left to the Royal Institution her husband's medals and diplomas and his scientific papers and apparatus, together with a sum of money to provide accommodation for them A large part of his apparatus, in particular that used in his low temperature researches, has remained at Albemarle Street since his death, and in recent years has been displayed in the Institution's collection The papers and objects now presented are additional material likely to be of great historic value to the Institution in relation to the period of Dewar's professorship Lady Dewar's other bequests include £4,000 to the Royal Society's Mond Laboratory at Cambridge and £3,000 to the Royal Academy of Music The residue of the estate is left for the furtherance of research in chemistry and physics at one of the Universities of Edinburgh, St Andrews, Glasgow or Aberdeen, or for the assistance of bacteriological research in connexion with the Royal Infirmary of Edinburgh and the Glasgow Royal Infirmary

Archæological Discovery in Honduras

AN important discovery in the ruins of Copan, the ancient city of the Maya in Honduras, is reported in *The Times* of February 21 An expedition of the Carnegie Institution of Washington, now working at Copan under Dr Gustav Stronsvik, in exposing a large stone staircase, has found an extensive system of canals and sewers connecting a massive series of buildings, which is now underground The buildings thus revealed include amphitheatres in which are monoliths and large statues in stone A statue of a warrior is described as of gigantic size Other

discoveries are cruciform rooms, of which the floors are covered with red paint, and among the artefacts are a number of bead-collars. Of even greater importance for the archæologist is a pair of solid gold boots, nearly two inches high, of exquisite workmanship. With two doubtful exceptions, objects of worked gold have not been found hitherto in that period of the Maya civilisation to which the ruins of Copan are assigned. Unless further and more intensive study should point to a foreign origin, these boots of gold must be accepted as evidence that the Maya added no little skill in this technique to their artistic accomplishment, and that a neglect of gold-working, which has always seemed somewhat surprising, has been attributed to them in error. Further details of the stone statues and monoliths will be awaited by archæologists with the greatest interest, as owing to the conditions of discovery, they should throw further light on the development of the Maya art of stone carving, for which the site of Copan is already remarkable among Maya remains.

COPAN, situated in the modern State of Honduras, lies in what was the southern area of Maya occupation, and was the fourth city to be founded after they had entered the country. It belongs to the 'Old Empire' or early Maya period and was occupied in at least the period from 195 A.D. until 540 A.D. This minimum period is derived from Mayan dates carved on stelæ found on the site, which are correlated with the Christian era according to a generally accepted interpretation. Copan is one of the most extensive and important of Maya sites. Its ruins consist of a vast complex of buildings which were reconstructed time and again in the course of occupation. Structural remains cover nearly the whole of the Copan valley. Recently, however, the site has suffered much from the effects of earthquake, and the river has begun to encroach on important parts of the ruins. In the circumstances, the Mexican Government has asked for the assistance of the Carnegie Institution's Expedition, which has had its headquarters at Chichen Itzá in Yucatan for some years and has had much experience in the restoration and preservation of Maya structures. Of this co-operation the present discovery is an outcome. Dr. Stronsvik reports, according to a communication issued by Science Service, Washington, that a part of the bank has collapsed into the river, and a beautifully carved chamber excavated fifty years ago by the late A. P. Maudslay, the well-known British archæologist, has fallen in. The landslide has left a vertical section of the ruins about a hundred feet in height on the eastern side. Dr. Stronsvik is of the opinion that the Maudslay chamber can be reconstructed, but the material carried away by the river is irrecoverably lost. As a minor mitigation, however, the landslide has revealed an instructive cross-section of the city's development.

Pygmy Man in India

A REMARKABLE report has come from Bombay of the discovery of the fossilised remains of a pygmy man in Baroda State. According to the account from the correspondent of *The Times* in the issue of February 21, the discovery was made at Vadnagar in the Mehsana district of Baroda. The remains were said to have been found in a prehistoric step well, 150 ft. long, and were those of a man 15 inches high. With them was a cow 18 inches high; nearby was a stick 10 inches high. The correspondent of *The Times* went on to point out that the discovery might call for a new orientation of theories concerning the cradle of the human race and the origin of civilisation which would no longer be traced to Java, or the valley of the Nile or the Indus, but rather to the valley of the Narmada. He also referred to Homer's story of the battle of the dwarfs and cranes and the report of Ctesias in the fifth century B.C. of the existence of a dwarf race in the heart of India. Even if the report were taken seriously - it has been stated to be a hoax—the discovery of a single specimen of so remarkably an aberrant character would be scant foundation "to prove the existence of an extinct race of pygmies more diminutive than that in Africa". Most ethnologists postulate a negrito strain in the Indian peoples which may have been derived from a diminutive race, not of some unknown extinct form, but analogous to one of the pygmy peoples, which extend, with intermissions, from West Africa to New Guinea, but these peoples are a highly specialised rather than a primitive type and their stature does not, as a rule, fall much below four feet six inches. Ethnological theory, for the moment, remains unshaken.

High-Altitude and Long-Distance Flights

THE Air Ministry has recently authorised the construction of two new experimental aeroplanes, one for high altitude and the other for long distance flights. The high-altitude machine will presumably be used for exploring the question of flight in the stratosphere, which is usually taken to mean that region in space above a height of 28,000 feet. There are plenty of aircraft in existence capable of reaching heights greater than this, the present record is 47,356 ft. held by the Italian pilot Donati, but no attempt has yet been made to deal with the possibilities of economical flight at such heights. The ultimate possibilities in this respect are much greater speeds owing to the reduced resistance of the rarified air. It will be necessary to carry superchargers to supply the required oxygen for the combustion of the engine fuel, appliances for breathing and heating, air-tight cabins or special suits for the occupants, and propellers the pitch of which can be changed to suit the different air conditions. These extras will have weight, which will reduce the fuel carrying capacity of the machine, and it is not impossible that this requirement alone will limit the practical utility of stratosphere flying.

THE time taken to climb to such heights will be considerable, which will possibly make the proposition not worth while except for long flights, where again lack of fuel capacity will place a limit on it. Such flights are not likely to have any immediate application to air transport, but their importance in the experimental sense is obvious. The long-range

experiments have a more definite application both to civil and service flying, where the question of the proper balance between quantity of fuel carried—to the exclusion of useful load—and the necessity for landing for further supplies, is essentially a practical one, peculiar to the geographical conditions in different parts of the world. These experiments should also further the development of the compression-ignition heavy-oil engine, the smaller specific fuel consumption of which makes it particularly applicable in this case.

Future of Lighter-than-Air Craft

THE announcement that the Secretary for the U.S. Navy will oppose any further construction of airships to replace the wrecked *Macon* presages the end of large rigid airship activities in that country. Germany is now the only country, so far as is known, to continue experiments with these craft in increasing sizes, the new larger Zeppelin, to be called the *Hindenburg*, being now near completion. It is significant that Dr. Eckener of the Zeppelin Company has succeeded where others have failed, probably because with faith and perseverance he has acquired that kind of knowledge and experience in design, and assembled a staff skilled in the technique of construction, maintenance and handling, which can only result from practical experience. Germany has now been building large airships continuously since 1910, and even up to 1914 claimed to have flown 80,000 miles and carried more than 37,000 passengers. The present *Graf Zeppelin*, launched in 1928, has crossed the Atlantic 62 times without serious mishap. The only large airship in the United States that is still in an airworthy condition, the *Los Angeles*, is a Zeppelin type built at Friedrichshafen.

IT is claimed nowadays that for long-distance commercial flying the airship is threatened by the large flying boat, which unquestionably has superior speed, but has not yet attained a comparable range. The latest projected flying boats only claim to be able to fly the Atlantic non-stop with a favourable wind. As a naval scout, if it can be protected from attack, the airship is still unrivalled. It can patrol trade routes far outside the range of aeroplanes, and its vision must be greater than any surface cruisers. It is also reasonably independent for action of the movements of its own surface vessels, a decided drawback of aeroplanes carried by the fleet.

Fundamentalism Undefeated

A CABLE message dated February 20 from New York which has appeared in *The Times* states that on the previous day the House of Representatives of Tennessee defeated a motion to repeal the State law which prohibits the teaching of any theory that man is descended from a lower order of animals. The vote against repeal was 67 to 20, and the opposition to the repeal was led appropriately by the oldest member of the House, who opened his case by reading the first chapter of Genesis. It will be remembered that about ten years ago a young teacher of biology, J. T. Scopes, was convicted and fined at Dayton under this law. The case aroused great controversy in the United States, and was outstanding because of the eminence and the oratory of the counsel employed on each side. Perhaps it was outstanding also as a picture of the simple faith which holds that truth can be decided by lawyer's arguments, and that scientific fact can be settled by majorities. Fundamentalism is by no means dead in Great Britain, but with the growth of knowledge it is dying.

Musk-Rats in Scotland

SINCE the musk rat campaign was commenced by the Department of Agriculture for Scotland, in October 1927, the official trappers have killed 945 individuals. To this must be added 60 killed by private persons, a total of 1,085, the progeny of five females and four males which escaped from an enclosure in Perthshire in 1927. Even the artificial pond on Gleneagles Golf Course has yielded five since the beginning of November 1934 (*Scottish Naturalist*, 1934, p. 11). As a rule, the traps were laid at the mouth of a burrow, and a remarkable fact is that they did much more damage to other wild creatures than to the musk-rats themselves. Mr. T. Munro, who supervised the work, records the death in traps set for musk-rats of 1,745 brown rats, 2,305 water-voles, 57 weasels, 36 stoats, 2,178 moorhens, 101 ducks, and a miscellaneous collection of birds, including amongst others 23 seagulls, 13 redshanks, 28 snipe, 15 blackbirds and a solitary kingfisher—a list of misadventures which runs to 6,587 items. It is possible that this very considerable slaughter cannot be avoided, but apart from the brown rats the majority of the wild creatures slain are harmless, if not even useful from the human point of view, so that every effort should be made to confine the work of the traps to the pests they are meant to capture.

Moving Biological Diagrams

MANY of the living processes of organisms can be illustrated most effectively by cinema films taken through the microscope, and with Mr. Walt Disney's technique, diagrams could be shown in the same way for educational purposes. The American Genetic Association has applied this principle in publishing "Biological Movie Booklets" to illustrate cell division, fertilisation and meiosis, and it proposes to deal later with the more intricate processes of heredity in *Drosophila*, crossing-over and so forth (Biological Movie Booklets. Vol. 1: Normal Cell Division. By Clyde E. Keeler. Pp. 46. Vol. 2. Maturation of Sperm. By Clyde E. Keeler. Pp. 94. Vol. 6: Fertilization. By Clyde E. Keeler. Pp. 65. Washington, D.C.: American Genetic Association, 1929. 3 vols., 1.50 dollars). Successively releasing the leaves of the booklets brings these dead diagrams to life, and for those who have not learnt to make the mental translation of diagrams into movement the effect should be improving. For those who have passed this stage the effect is still amusing, provided that the leaves are turned over quickly. Taken separately, however, the figures seem to be drawn, not from life but from an early or popular textbook. The

descriptive text is correct for 1908. The draughtsmanship is not expert and the drawings should have been reduced from a larger size to conceal its defects. If a future generation is to learn its biology this way, it is to be hoped that the publishers will take their task more seriously and remedy these shortcomings.

Acquisitions at the British Museum (Natural History)

RECENT acquisitions by the Department of Zoology include a specimen of the frilled shark (*Chlamydoselachus*) caught by a trawler off the west of Ireland. This is the first occasion on which this species has occurred in British waters. It was first discovered off the Japanese coasts. The frilled shark is of great interest on account of the many primitive characters which it possesses. The mouth is at the end of the snout, instead of being underhung as in most living sharks. There are six gill openings on each side instead of the usual five, and the teeth are of a curious comb like shape. The body is much more slender and eel-like than in other sharks, and in several ways it approaches some of the very ancient types of fossil shark-like fishes. Through the generosity of the trustees of the Salisbury, South Wilts and Blackmore Museum, the Department of Geology has received a large number of fossil invertebrates and fishes, forming part of the collection made by the late Dr. H. P. Blackmore from the Chalk in the vicinity of Salisbury. A further valuable instalment of 488 specimens of Swiss minerals, representing 59 carefully recorded localities, collected by himself, has been presented by Mr. F. N. Ashcroft to the Department of Minerals.

THE Department of Botany has received a bequest of Mr. T. J. Foggitt's British herbarium. This numbers 4640 sheets of well-gathered and beautifully preserved plants. Mr. Foggitt was a well-known Yorkshire botanist, the son of the T. J. Foggitt who collaborated with J. G. Baker in the formation of the Botanical Exchange Club which brought Thirsk into botanical prominence in the sixties of last century. The herbarium is rich in Yorkshire plants, and is a welcome addition not only for this but also on account of the large number of extremely rare plants it contains. The Siamese collection of Dr. A. Marcan has been purchased. It contains abundant material of 2772 numbers including several co-types. It has been named for the most part by the late Prof. W. Craib and Dr. A. Kerr. The collection forms a valuable addition to the Department which is weak in Siamese plants. A further set of Dr. H. Schlieben's Tanganyika plants numbering 146 has been purchased. The first two fascicles of Lundell and Nannfeldt's "Fungi exsiccati suecici praesertim Upsalienses" has been presented by the Elias Fries Committee. This exsiccata is of especial interest as it consists mainly of fungi collected in the neighbourhood of Uppsala, a region made famous by the classical works of Elias Fries.

Rural Electrification in Russia

ONE of the results of the first five-year plan is to change fundamentally the character of farm work in the U.S.S.R. Instead of a million small holdings, there are now only some thousands of large collective agricultural and pastoral farms. Horse traction and manual labour are rapidly being replaced by the mechanical tractor and electrically driven machines and implements. Electrification is the key note of the industrial reorganisation of the country. In the *Electrical Review* of February 22, G. Shapiro gives a description of some of the new agricultural and dairy farming methods. Experiments on electrical haulage and electric tractors for ploughing have proved most satisfactory. The electric tractors used for ploughing were usually converted mechanical tractors in which the internal combustion engines had been replaced by electric motors. The results show a considerable saving in working expenses. Excellent results are being obtained with electric threshing, which is developing very rapidly. These machines are produced in Kharkov, and are driven by electric motors. Electrically driven machines have also been successfully experimented on in connexion with vineyards, tea plantations and cotton fields. In dairy farms, electricity will be used for milking, cleaning the animals, preparing food, water pumping, ventilation, butter making, cheese making and lighting. Pig farms and poultry farms also take an appreciable electric load. Researches are being made on the heating of the soil and the influence of light and various rays on seeds, roots and poultry and animal breeding. By the end of the second five year plan (1937), it is anticipated that about 30,000 stations will be threshing electrically and will cover a sowing area of about 30 million acres.

Aerodrome Lighting for Night Flying

OWING to the steady increase in the number of passengers and in the volume of the mails carried by aeroplanes, the proper lighting of aerodromes has become of great importance. In the *G.E.C. Journal* of November, Mr. W. A. Villiers describes the equipment produced by the General Electric Company for this purpose. The problem is to give the pilot of an aeroplane flying on a dark night the guidance he requires to make a safe landing. In many cases at the present time, aerodromes are only a few miles apart, he must therefore be able to identify the place with certainty. This is done by means of a beacon. The light must be visible in all weathers, but must not be dazzling. The colour and character of the light should be different from that given by neighbouring beacons. The beacon is in the shape of a truncated cone about 14 ft. high, formed of six hairpin-shaped neon tubes giving the usual red neon colour. It has low intrinsic brilliancy, but in favourable weather conditions can be seen at a distance of 50 miles. The identification is usually effected by making it flash in Morse characters the initial letter of the aerodrome. The boundary of the landing place is marked out by electric lamps inside orange glass globes. All landings are made against the wind as this direction gives the safest landing. The landing ground should always be flood-lighted, the space being so large that even the fastest aeroplane does not overrun the lighted area. Nine Osram lamps

each taking a kilowatt are used for this purpose. Views are shown of the flood lighting employed at Croydon air-port.

American Amaryllis Society

THE first year book (1934) of this Society has recently been published under the editorship of Dr Hamilton P Traub (Orlando, Florida, 2 dollars) Plants belonging to the genera *Amaryllis*, *Hippeastrum*, *Crinum*, *Zephyranthes*, *Alstromeria* and others are the special objects of the Society, though its interest can reasonably be expected to include such well-known plants as snowdrops, daffodils and snowflake (*Leucojum*). A useful classification for show purposes has been prepared, and the Fischer colour chart has been adopted as the standard of colour nomenclature Botanical descriptions of the Amaryllideæ according to Baker are given, and many pages are devoted to the breeding of the various species Other sections deal with propagation and culture, whilst insect pests and diseases receive brief mention Storage, forcing and marketing are also discussed One of the most noticeable features is the brevity of each contribution, for nearly seventy articles are included in the 102 pages of the volume The memory of Henry Nehrling, a noted raiser of *Amaryllis* plants, is honoured by dedication of the first year book

The Observatories Year Book 1932

THIS important publication of the British Meteorological Office (Air Ministry) contains a very large mass of meteorological and geophysical information, obtained at the five observatories of Lerwick, Aberdeen, Eskdalemuir, Valencia and Kew, together with upper-air observations made by sounding balloons (London H M Stationery Office.) Its appearance has been slightly delayed owing to a change in its mode of production hitherto it has been printed, but in the present issue most of the extensive tabular matter, and part of the text, is reproduced direct from typescript by the Replika process of Messrs. Percy Lund, Humphries and Co, Ltd There is a certain loss in legibility and appearance, but this disadvantage is on the whole outweighed by the reduction in cost thus achieved, the reduction is passed on to the purchaser, since the "Year Book" now costs two guineas (postage extra) instead of three as for the preceding volumes The volume provides a very important record of the meteorological and magnetic conditions over the British Isles during 1932.

American Expedition to Tibet

AN expedition of the Academy of Natural Sciences of Philadelphia has recently left Yachow in Szechwan Province, China, for a year's survey of the zoology of eastern Tibet. The party is under the leadership of Brooke Dolan of Philadelphia who, with some of his staff, has had previous experience in the western China area Its main object is to obtain information and material for habitat groups of typical Tibetan animals, such as the wild yak, wild horse, ammon sheep, snow leopard, Tibetan gazelle and bear; and as an aid to this end motion pictures will be taken of the wild game, which is said to be abundant on the high steppes of Kuku-nor and Tsaidam Mr Dolan's party is working in co-operation with the Metropolitan Museum of the Academia Sinica in Nanking It is gratifying to find that expeditions in out of the way parts of the world are concentrating more upon observation of animal distribution and habits than upon the unrestrained collecting which was often divorced from any sort of ecological observation

Age of a Stone Curlew

A SHORT note (*Proc Roy Zool Soc N S Wales*, 1933–34) records the presence in a suburb of Sydney of a fine specimen of stone curlew, which has attained a great age for such a bird He was brought to Sydney in his third year, and by the end of 1934 he will have passed his twenty-ninth birthday, during all the time he has been allowed absolute freedom in the garden More information regarding this interesting bird would have been welcome On what has it been fed during these years, for the food of waders is not always easy to obtain? Also, has it ever shown any movements suggestive of a desire to migrate at the proper season?

International Inquiry into Television

THE Rome correspondent of *The Times* states that the executive committee of the Institute of Educational Cinematography has decided to set up an international committee to study the problems raised by television The committee, which will be composed of representatives of national organisations in Europe and America interested in television, will inquire into the condition of television in the various countries and the questions raised by its practical utilisation; the relations between television and cinematography; and the use of television for cultural and educational purposes

Scientific Research in Japan

THE report of the National Research Council of Japan for the year ending March 1933 shows that, during the year, meetings of the following divisions of the Council were held. administration, astronomy, geophysics, chemistry, physics, geology and geography, agriculture, medical sciences, engineering and mathematics. Each division has sectional committees which deal with branches of the work, as for example, dyestuffs, industrial research and radio research; and delegates attended the meetings of the International Unions of Astronomy at Cambridge, Mass, and of Mathematics at Zurich. The urgent necessity of encouraging and supporting scientific and industrial research has led to the formation of a "Foundation for the Promotion of Scientific and Industrial Research of Japan" which was incorporated in December 1932 with an annual Government grant of 700,000 yen for current expenses.

Lectures for Students in Secondary Schools

WITH the view of stimulating interest in science and its contacts with everyday life among pupils in secondary schools, the British Science Guild has inaugurated a new series of lectures by eminent men of science to pupils from such girls' schools in London. The first of the series will be by Mr. C. C. Paterson, director of the Research Laboratories of the General Electric Company, who will lecture on "The Electron Liberated: its Industrial Consequences". The lecture will be given to pupils from schools north of the Thames on Monday, March 25, at 5.0 p.m. in the Lecture Theatre of the Institution of Electrical Engineers, Victoria Embankment, London, W.C.2, and will be repeated to the group of schools south of the river on Wednesday, March 27, at the same hour.

Memorial to Sir Edgeworth David

IN order to ensure a memorial worthy of Sir Edgeworth David, the geologist and explorer, who died on August 28, 1934, a meeting has been held in Sydney which included representatives from the business, professional, scientific and academic life of the city, and the following resolution was adopted: "In view of the great work done by Sir Edgeworth David for the science of geology and in view of the outstanding importance of his teaching, research, and contributions to geological knowledge as the first Professor of Geology in the University of Sydney, the Committee resolves (1) that a fund to be known as the David Memorial Fund be raised, that it be handed over to the University of Sydney, and that the income from it be applied in such manner as the Senate thinks will best aid in the advancement of the science of geology; and (2) that the Senate be requested to associate the name of Sir Edgeworth David permanently with the Chair of Geology." Further information can be obtained from the Honorary Treasurers, David Memorial Fund, Science House, Gloucester Street, Sydney.

Announcements

HIS MAJESTY THE KING has been graciously pleased to accord his patronage to the Institute of Chemistry of Great Britain and Ireland. The Institute, which was founded in October 1877, celebrates this year its charter jubilee, having been incorporated by royal charter granted by H.M. Queen Victoria in June 1885.

THE University of Toronto has awarded the Charles Mickle fellowship for 1935 jointly to Dr. Edward Mellanby and Mrs. May Mellanby. The fellowship is endowed under a bequest by the late Dr. W. J. Mickle, and is awarded annually "to that member of the medical profession who is considered by the Council of the Faculty of Medicine of the University of Toronto to have done most during the preceding ten years to advance sound knowledge of a practical kind in medical art or science".

MR. H. J. POOLEY, general secretary of the Society of Chemical Industry, who was the first student to go through a course of chemical engineering at a British university - Liverpool 1894-98 - has been awarded the Osborne Reynolds medal for meritorious contribution to the progress of the Institution of Chemical Engineers. The medal, which was first awarded in 1928, is in honour of Prof. Osborne Reynolds (1842-1912), whose researches on heat transmission and the flow of liquids are extremely important to the chemical engineer.

IT is announced that the dates for the May and June soirées of the Royal Society have been altered to Friday, May 3 and Friday, June 14.

THE German Röntgen Society has recently had a memorial tablet erected to Röntgen at Pontresina in the Engadine, where for more than forty years he spent his annual holiday.

AN exhibition of hygiene will be held in Strasbourg on April 6-22 to demonstrate scientific, administrative, industrial and commercial progress in the field of hygiene and sanitary technique, particularly as regards corporal hygiene, school hygiene, housing, clothing, diet and sport. Further information can be obtained from Services Administratifs, Hôtel de Ville, rue Brulée 9, Strasbourg.

THE Association of Special Libraries and Information Bureaux (ASLIB) is to hold its twelfth annual conference at St. John's College, Cambridge, during the week-end beginning Friday, September 20. Particulars may be obtained from the Secretary of the Association, 16 Russell Square, London, W.C.1. Sir Richard Gregory has agreed to accept re-nomination as president of the Association for 1935-36.

ON the initiative of the Italian Society of Criminal Anthropology and Psychology, a meeting was recently held in Paris, attended by the Minister of Justice, numerous leaders of the French medical and legal professions, members of the French society of criminal prophylaxis and various foreign representatives, to discuss a proposal to found an international society of criminal anthropology and psychology. After acceptance of the proposal, it was agreed to hold the first congress of the society in Rome next October.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant secretary to the British Association—The Secretary, British Association, Burlington House, W.1 (March 11). A principal of the Barrow-in-Furness Technical College—The Director of Education, Town Hall, Barrow-in-Furness (March 12). A probationer naturalist (male) on the scientific staff of the Fishery Board for Scotland—The Secretary, 101 George Street, Edinburgh, 2 (March 18). A reader in sociology at Bedford College—The Academic Registrar, University of London, S.W.7 (April 1). A William Prescott professor of the care of animals in the University of Liverpool—The Registrar (April 23).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 346.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Laws of Shell-Growth in English Native Oysters (*Ostrea edulis*)

ON investigating recently an economic problem on growth in the native oyster, *Ostrea edulis*, close relations were found between volume and weight of the entire animal, and both mean diameter and mean axis of the shell (mean axis being the mean of the described[1] dimensions of length, breadth—or height zoologically, and width—or thickness) As oysters are measured in wooden tubs (4 'wash' = one 'tub') on the oyster-beds and mean diameter is the simplest criterion of size, volume and mean diameter are the most interesting relations economically Volumes and mean diameters for Essex native oysters from Roach River are given in Fig 1, R^1, and show a close approximation to the relation $y = 0{\cdot}0404\ x^{3\cdot531}$ where y is volume in c.c. and x = mean diameter in cm The plottings are of samples of 10–40 oysters estimated at 2, 2 or 3, 3, 4, 4 or 5, and 5 years of age, with additional samples of small oysters, for which I am greatly indebted to Mr. Austin Gardner and M Rigoine de Fougerolles Samples of tiny oysters grown in 1934 in the sea were obtained living on a limed tile from France and are plotted, since English spat attached to shell are difficult to detach whole, and any difference between English and French spat is estimated to be non-significant on the scale shown

It is clear that a definite law of growth exists irrespective of rate and notwithstanding the range of individual variation which will be discussed later It can be shown that, for any given increment in average mean diameter, the average increase in volume is successively approximately 11 56 times, 4·19, 2·76, 2·20, 1·90, 1·72, 1·60, 1 52, 1·45, 1·40 and so on · thus from ½ in to 1 in the increase in volume is 11 56 times or 1,056 per cent; from 1 in to 1½ in 4·19 times or 319 per cent; from 1½ in to 2 in. 2·76 times or 176 per cent; 2 in. to 2½ in. 2·20 times or 120 per cent; 2½ in. to 3 in. 1 90 times or 90 per cent. Similarly, the increase in mean diameter from 1 cm to 2 cm. is 11·56 times and from 2 cm. to 3 cm 4·19 times and so on; and from 0·5 cm to 1 cm. 11·56 times and from 1·0 cm. to 1·5 cm 4 18 times and so on

It is known that the rate of growth of the shell varies locally with habitat and from season to season[2] with environmental conditions, and that therefore there is no special size for a given age. Nevertheless, age can be estimated empirically from local knowledge to within one year in a fair proportion of shells. The estimations plotted in Fig. 1, R^1, are subject to these limitations; for example, groups 2–3 and 4–5 were put in intermediate classes; most of the shells showed uniformly good growth.

Experiments in the sea on the growth of Essex native oysters in the first and second year have been made over a long period[2], and one sample has been reared into the fourth year. This sample was taken out of the sea in the summer of 1927 when the fourth year's growth had begun. two of the largest of these are plotted in Fig 1 (WM^1). A few oysters reared

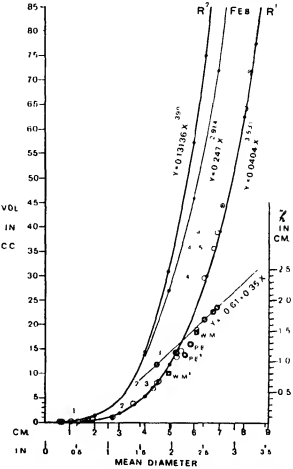

FIG 1 Laws of shell-growth in some habitat races of *O. edulis*.

R^1 relation between volume of the entire living animal and mean diameter of the shell in Roach River, Essex natives. October 1934

R^2: relation between volume and mean axis in the same material as used for R^1 October 1934.

F.E.B approximate relation between volume of the entire living animal and mean axis of the shell (with mean diameter reduced by the amount of new shell shoot). Fal Estuary, East Bank. November 1934.

Samples are shown by open circles of different kinds; individuals by circles with large central dots, and calculated points by dots; the numerals 1, 2, etc., give the estimated age in summers of adjacent samples. *W.M*, *P.E*, experimental samples from West Mersea, and Port Erin ponds.

Slopes and constants of the log-graphs are close approximations and are modifiable for immaturity.

in the Port Erin tanks[3] and examined in the third summer of growth (1934) during the growth period are also plotted in Fig. 1 ($P.E.^1$). In these two cases new thin shell shoots have rapidly increased the mean

diameter without an immediate commensurate increase in volume[4] The samples and experiments illustrate the wide range of variation in annual rate of growth, and indicate that well thought out and long standing experiments in the sea are needed in different localities to obtain satisfactory data correlated with the environmental conditions It is hoped to begin such experiments in the near future

The relation of mean axis lies somewhat closer than mean diameter to volume and offers a better criterion of comparison between different stocks of oysters The difference between certain types of Essex natives and Fal Estuary bank oysters already noticed[4] is given definite expression in the deduced graphs (see Fig. 1, R^4 and *FEB*) for the relation of volume to mean axis, details of which will be published later

The resemblance of the shape of *O edulis* to a segment of a sphere is real, since the 'heights' (h) of segments of spheres having the same volume and mean diameter as the major oyster samples noted above give the straight line graph in Fig. 1, within experimental error, when plotted against mean diameter. (Prof L Rosenhead kindly gave me a formula for finding unknown heights from given diameter and volume) The fundamental shape of this oyster is therefore a function of that of a segment of a sphere; for a definite relation also exists between segment heights and observed oyster widths, as will be shown when the subject can be treated more fully at a later date.

Detection of Nuclear Disintegration in a Photographic Emulsion

IT has been shown recently by Chadwick and Goldhaber[1], and by Fermi and his collaborators[2], that some light nuclei, particularly lithium and boron, are disintegrated by slow neutrons In the case of boron, the mass-energy relations seemed best satisfied by assuming a disintegration into three particles[1] The simplest reaction, namely.

$$B^{10} + n^1 \rightarrow Li^7 + He^4 \quad . \quad . \quad . \quad . \quad . \quad (1)^1$$

should, according to the accepted masses of the particles, release some two million e volts more energy than is observed. Unless the existence of new isotopes, He^6 or Li^6, of improbably low masses, be assumed, no other disintegration into two particles would fit the mass-energy relations.

To decide the type of reaction directly we have made use of the following method. A photographic plate was soaked in a solution of borax and then dried, thus introducing boron into the gelatine. The plate was then exposed for 15 hours to a radon-beryllium neutron source of strength 80 millicuries, enclosed in a thick lead cylinder to reduce the effect of the gamma-rays. Both source and plate were surrounded by paraffin.

One of us (H. J. T.) has worked for some time on the detection of fast particles by the tracks produced in photographic emulsions. By the courtesy of the research staff of Messrs. Ilford, Ltd., new types of plate have been prepared specially suitable for this work, and we have used these special plates in the present experiments

The plate impregnated with borax shows, under a high magnification, numerous short straight tracks, of which the equivalent length in air is $1 \cdot 1 \pm 0 \cdot 1$ cm. There are some 50,000 such tracks per sq cm of the plate A photomicrograph of one of the tracks is reproduced (Fig 1 × 1250) Control experiments with untreated plates show that the tracks cannot reasonably be ascribed to any other cause than the disintegration of boron by slow neutrons

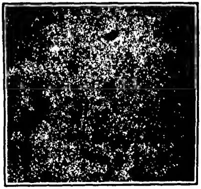

FIG 1

Tracks of this kind cannot be due to a three-particle disintegration, and we must therefore conclude that the disintegration takes place according to reaction (1), which requires that the mass of the B^{10} atom should be $10 \cdot 011 \pm 0 \cdot 001$, the other masses being known to within fairly narrow limits

Note added in proof · In a similar way, by using a salt of lithium, we have obtained tracks which correspond to the reaction

$$Li^6 + n^1 \rightarrow He^4 + H^3 \quad . \quad . \quad . \quad . \quad . \quad (2)^1$$

The length of these tracks represents the sum of the ranges of the two resultant particles, and is found to be $6 \cdot 9 \pm 0 \cdot 2$ cm air.

Directed Diffusion or Canalisation of Slow Neutrons

IT has been shown by Fermi and his collaborators[1] that the efficiency of radioactivation of certain elements by neutron bombardment is greatly increased by surrounding them with water, paraffin or similar hydrogen-containing substances This effect is attributed to multiple collisions between neutrons and protons, similar to those due to the thermal agitation of gas molecules, producing reduction in speed of the neutrons, which facilitates capture by other nuclei

It was pointed out to us by Dr Leo Szilard, who was then working in this laboratory, that this retardation by diffusion should afford a possible method of controlling the direction of propagation of slow neutrons. The mean free path of slow neutrons between successive collisions with protons is considerably less than their range in air. Consequently,

it was anticipated that a stream of slow neutrons would diffuse more readily along an air column contained in a tube having walls composed of a substance of high hydrogen content, than through the walls themselves

We have verified Dr Szilard's prediction in the following manner Neutron sources consisting either of about 100 millicuries of radon with beryllium, or of 150 milligrams of radium in tubes surrounded by beryllium, were embedded in paraffin blocks 10 cm in diameter and 10 cm high, and placed inside a large cavity in the base of a hollow cylinder of paraffin wax. The walls of the cylinder were 7–10 cm thick, and its length could be altered by the addition of a number of similar sections of 12 cm internal diameter The intensity of the neutron beam at various distances from the source was measured by the radioactivity induced in thin pieces of silver or rhodium or in iodine, the activity of the detectors being measured by a Geiger-Muller counter

In this way, appreciable radioactivation was obtained at distances exceeding one metre from the source A right angle bend in the tube reduced the intensity of the neutron beam by about 30 per cent To obtain the maximum canalising effect, it was found necessary to avoid all gaps in the walls and to close both ends of the canal with wax A tube of pure graphite gave a smaller but definite canalising effect, but none was observed with a tube of adulterated ebonite

Fuller details of these experiments will appear in a forthcoming issue of the *British Journal of Radiology*, and other observations will be published independently by Dr Szilard

The Absolute Field Constant in the New Field Theory

IN the modification of Maxwell's theory proposed by one of us[1], the notion of an 'absolute field', called b, played an essential part In the electrostatic case, the universal constant b is simply the upper limit of the field strength, whilst in the general case of an arbitrary field, b sets a limit to the possible values of $\sqrt{(\vec{E}^2-\vec{H}^2)}$, when $\vec{E}$ and $\vec{H}$ are calculated in that Lorentz frame in which the Poynting vector vanishes in the given world-point (In the exceptional case when there is no such Lorentz frame, that is, if $\vec{E}$ is perpendicular to $\vec{H}$ and $\vec{E}^2 = \vec{H}^2$, there is no limit) Born and Infeld[2] have calculated b from the experimental values of the charge e and mass m of the electron by equating to mc^2 the total energy of that centrally symmetrical electrostatic solution which has the total charge e By this procedure b works out to be $9{\cdot}18 \times 10^{15}$ E.S.U

We now believe that this determination may be wrong, notably too high, because the spin had been neglected. Since the solution for the spinning electron cannot yet be calculated, we must content ourselves with giving a rough estimate Let μ be the magnetic moment of the spin and r' the *new* radius of the electron (to be calculated here) and let us try tentatively to account for the observed mass m by the energy of the spin only (neglecting the electrostatic energy). The following statement will then be correct as to order of magnitude

$$\frac{1}{2}\frac{\mu^2}{r'^3} - mc^2$$

We can assume that μ is Bohr's magneton

$$\mu = \frac{eh}{4\pi mc^2} = \frac{e}{2}\,\frac{e^2}{mc^2}\,\frac{hc}{2\pi e^2} = \frac{er_0}{2\alpha},$$

where

$$\alpha - \frac{hc}{2\pi e^2} = \frac{1}{137{\cdot}2},$$

the fine-structure constant, and $r_0 - e^2/mc^2$, the quantity usually called the radius of the electron, it is connected with the electronic radius r_{el} of the new field theory by the equation

$$r_{el} = 1{\cdot}236 r_0$$

From our first equation we find now

$$r' - \frac{r_0}{2\alpha^{2/3}} = \frac{r_{el}}{2{\cdot}472 \times \alpha^{2/3}} = 11 r_{el}$$

Since r' is considerably larger than r_{el}, the electrostatic energy in the new model will be a small fraction of mc^2, and we are justified in neglecting it for our rough estimate

Again, the field 'in the interior' of the magneton may safely be equated to the absolute field b, which fact, as to the order of magnitude, will be expressed by

$$b - \frac{\mu}{r'^3} - \frac{2mc^2}{\mu} = 4\alpha\,.\,\frac{e}{r_0}\,.\,\frac{mc^2}{e^2} - 4\alpha\,\frac{e}{r_0^2}.$$

This is to be compared with the value, say b_{el}, formerly calculated from the electrostatic energy

$$b_{el} - \frac{e}{r_{el}^2} = \frac{e}{(1{\cdot}236 r_0)^2}$$

We have

$$b = 4(1{\cdot}236)^2\ \alpha\ b_{el} = \frac{b_{el}}{22{\cdot}5}.$$

If the estimates are not too rough, the new point of view increases the radius of the electron by a factor of about 10, and decreases the limiting field to about the twentieth part

The Hypothesis of Continental Drift

THE late Dr. A. Wegener claimed the advantage for his hypothesis of 'continental drift' that it could be tested by making repeated astronomical observations of the positions of land stations; for drifts at the rates of only a few feet a year would suffice to carry the land masses far within the span of geological time. Few geologists would in respect to this problem deny the applicability of the dictum that 'the present is the key to the past'; the question is whether precision determinations of 'position' will give measurable results within a reasonable time.

In 1932 Herr Hans Jelstrup determined the

longitude of Sabine I, East Greenland, and comparing his value with that of Börgen and Copeland's (1870) he finds a westerly drift of 615 metres. Owing to uncertainties inherent in the methods used in 1870, this figure is unreliable, but Herr Jelstrup concludes that at least 250 metres of the apparent drift is a real one, and he expresses the hope that it will be possible to repeat his observations in, say, 1942 to establish the fact of drift beyond all possible doubt[1]

Herr Jelstrup's results would seem to warrant the initiation of an investigation of the matter as a world problem by fixing now the positions of a network of stations, so that by future observations the reality of 'continental drift' may be settled one way or the other in the lifetimes of at least the younger of us The stations must be chosen with due regard to geological situation To examine 'continental drift' we shall want them on the great 'shields'- especially on extensive 'crystalline massifs', the so-called 'stable blocks' That large horizontal displacements have taken place in the 'mobile belts' of the crust is known and it would be valuable to have stations on such belts which show activity at the present day, for example, the East-Indian island arcs, so that the movements of the 'stable blocks' may be related to the crumplings of the 'mobile belts' Such results cannot fail to throw light on the mechanism of mountain building, and there is good reason to believe that it will now be possible to raise the study of crustal movements to a science by obtaining quantitative data

The time has come for some international body to take up the matter (1) to inquire what stations, such as the great observatories, have been determined with sufficient accuracy to be of use, (2) to consider what further stations shall be established, and (3) to organise periodic redeterminations every five or ten years in the future

Action of Thyroid Extract on the Respiration of Tissues of Invertebrates

THE respiration of fresh tissues (whole and macerated), and of dried and powdered tissues of various invertebrates with and without the addition of thyroid extract, was measured in the Barcroft Warburg apparatus (in Ringer solution, sea-water, normal saline or water, according to the tissue)

It was found that in the case of eggs of insects-mono-voltinic *Bombyx mori* during æstivation and incubation (1st and 3rd stages of egg development)-thyroid extract caused an increase of oxygen consumption up to 23 per cent; on hibernating eggs the effect of thyroid extract was even more marked, and oxygen consumption was increased up to 3,700 per cent The experiments were carried out at temperatures of 17°-37° C With whole and various portions of the silk-glands of *Bombyx mori*, oxygen consumption was increased up to 15 per cent.

Echinoderma An increase up to 300 per cent was noted with unfertilised eggs and with ovaries of *Spherocinus granularis*.

Crustacea. With fertilised eggs in all stages of development of *Carcinus mænas, Eupagurus prideauxii, Portunus corrugatus* and *Portunus holsatus* an increase up to 300 per cent was noted

Mollusca With fertilised eggs of *Aplysia limacina*, an increase up to 220 per cent was noted

Tunicata With the ovary of *Ciona intestinalis* an increase of oxygen consumption up to 360 per cent was noted

In every case the action of the thyroid extract was *identical on the uninjured and freshly macerated tissues*

The action of the thyroid extract was even more marked on suspensions of tissues which had been dried and powdered, for example, increase of oxygen consumption was noted up to

5,000 per cent	with powdered	eggs of *Bombyx mori*,
3,000 ,, ,,	,, ,,	silk glands of *Bombyx mori*,
9,300 ,, ,,	,, ,,	ovary of Echinoderma,
4,000 ,, ,,	,, ,,	eggs of Crustacea,
2,700 ,, ,,	,, ,,	eggs of Mollusca,
30,000 ,, ,,	,, ,,	ovary of Tunicata

The influence of thyroid extract on oxygen consumption is almost instantaneous and lasts up to 20 minutes In the case of suspensions of powdered tissues which have been standing for months (eggs and silk glands of *Bombyx mori*) and show almost zero oxygen consumption, the addition of thyroid extract causes an almost immediate restoration of oxygen consumption

Solutions of potassium cyanide did not diminish the action of thyroid extract on suspensions of dried and powdered eggs of *Bombyx mori*, the cyanide alone, in the absence of thyroid extract, was found to increase the oxygen consumption of this suspension

All the experiments are made with the thyroid extract 'Elyteran' (Bayer) Synthetic thyroxin was found to have no effect at all on oxygen consumption Full details will be published elsewhere

Anæsthesia Produced Electrically

IN his letter entitled "Testing for Unconsciousness after an Electric Shock", in NATURE of January 19, Capt C W Hume expresses the opinion that the electric stunning of animals is based on dogmatic assertions He need not fear that research in this matter will not be welcomed by all concerned, or that any inquiry, based on actual investigation, will be stifled It is, however, only a matter of time before such research confirms the opinions expressed by eminent physiologists in favour of electric anæsthesia for animals

The points raised by Capt Hume do not help to clarify matters; in fact, argument from such premises is liable to confuse the issue They may be commented on as follows.

(1) The subject referred to is a human being Animals are very much more susceptible to electric shock than humans as shown by the extraordinary cases of animal electrocution on record There is no evidence of the existence of a 'nightmare state' in the case of animals

(2) The interrupted D C used by Regensburger and Hertz is weak compared with the sinusoidal A C used in electric stunning if maximum values be considered A 10 per cent interrupted D C giving a meter reading of 31 milliamp is really a current of 310 milliamp 0 5 amp R M S A C represents a maximum current of 710 milliamp It is beyond doubt that the stunning effect depends on the strength of the current and not the length of time for which it is applied The A C is therefore twice as effective as the intermittent D C used by Regensburger and four times that used by Hertz

(3) The current strength applied in electric stunning is considerably above that required to produce immobility during application only It has been noted that, with animals, a low current just sufficient to paralyse produces rigidity A higher current invariably produces relaxation, and it is only when this state is reached that pain unconsciousness is assured

(4) and (5) It must be definitely stated that experiments on human beings do not prove anything with regard to the effect of electric current on animals such as sheep and pigs, and cannot logically be cited in this connexion Further, the fact that Hertz's experiments were carried out on incurable invalids means that the results are not necessarily valid for healthy subjects In my experience, the animals that are difficult to stun electrically are those that are unhealthy In particular, a pig which would not stun properly was found to be tuberculous

(6) The 'nightmare state', whether it be produced or not in animals as in human beings, implies insensibility to pain In electrical accidents, severe burning has been felt only as a 'stinging sensation'

(7) If muscular contraction persists in an animal for more than a second, either the current is too low, the electrodes improperly applied or the animal unhealthy In actual practice, almost all animals under proper conditions of electric stunning relax instantly and remain relaxed until normal post mortem reflex action commences

Moulting and Replacement of Feathers

MY attention has been directed to a letter in NATURE of January 26 from Miss Anne Hosker In this letter, Miss Hosker states that I am wrong as regards the statement made in my paper[1], namely, that "As compared with other bird-groups the condition (of moulting in the penguin), as far as I am aware, is absolutely unique"

In the specimen on which the statement was founded (which can still be seen in the British Museum, Natural History), almost fully grown new feathers can be exposed, on dissection, occupying the highly specialised feather follicles embedded in the subcutaneous tissue (cf. loc. cit text-figures 6 and 7) They can be cut out of those follicles, dried and demonstrated to be nearly as large as the old feathers about to be shed, and of course more perfect, while, as I stated, the tip of the new feather, if still in continuity with the old, is thrust through the lower umbilicus and pushes the old feather before it, so that the latter may be as much as nearly a quarter of an inch distant from the outer surface of the skin In other words, the new feather is already fully formed and ready to come through before the old feather is shed

If this can be proved not to be a unique phenomenon in the avian world, I think most ornithologists will be greatly surprised, but after reading Miss Hosker's letter I would beg leave to make the suggestion that perhaps she and I have been writing about two different things Miss Hosker seems to have been dealing with the well-known mode of development of the series of prepennal and pennal feathers as they first emerge from the chick On the other hand, I was dealing in my paper with the wonderful adaptation to be observed in the penguin when moulting, an adaptation the object of which is obviously to lose as little time as possible, since until the penguin has completed its moult it cannot enter the water and so has to starve

Molecular Spectrum of Cadmium Vapour

PROF ROBERTSON's observation[1] of a maximum at 2212 A in the spectrum of an arc between cadmium electrodes which is much more intense than the cadmium band at 2125 is very interesting This observation is surprising in view of the fact that no maximum at 2212 was observed by Cram[2] in fluorescence or Tesla discharge, while the 2125 band was easily observed both in fluorescence and discharge The condensed copper spark giving more intensity near 2212 than 2125 when used as source for fluorescence excited 2125 with no emission maximum at 2212 These two bands have nearly the same intensity in absorption The failure of an emission maximum at 2212 to appear along with the 2125 band of cadmium in fluorescence and discharge in pure cadmium vapour shows that the 2212 maximum is likely to be due to an impurity The opportunity for observing spectra due to impurities (such as CdO, CdH, etc) is always much greater in the arc in air than in a quartz tube containing only pure cadmium

The earlier reproductions of the spectra of electrodeless discharges through cadmium vapour given by Robertson show a maximum at 2212 at low pressure but no 2212 maximum at high pressure This favours the view that the 2212 maximum comes from an impurity the relative importance of which in the vapour is less at high cadmium pressures. Cram failed to observe an emission maximum at 2212 in cadmium vapour at any pressure

If we consider the corresponding bands of zinc and mercury, the following similarities are observable. Let B represent the bands Zn 2060, Cd 2212, Hg 1808 and C the bands Zn 2000, Cd 2125, Hg 1692. In absorption, the intensity of B is greater than or equal to that of C. In emission from a Tesla discharge through the vapour at pressures of 10-40 mm, C is much more intense than B. In most cases B was not observed at all In contrast, Robertson observed in the cadmium arc spectrum an emission maximum corresponding to B much more intense than C. This would indicate either that conditions in the cadmium arc were especially favourable to emission of B or that the 2212 emission maximum was due to an impurity

Since learning of Robertson's results, we have photographed the spectra of arcs with electrodes of

carbon, and zinc or cadmium, with the carbon positive. The spectra are shown in Fig 1 The cadmium arc shows the emission maximum at 2212 but the zinc arc does not show a corresponding maximum at 2060 This failure of 2060 is probably not due to insufficient vapour pressure of zinc in the arc since the reversals of the zinc and cadmium resonance lines are approximately equal in width, and the intensity of B and C relative to the resonance

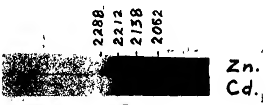

FIG 1

lines in absorption is about the same for zinc and cadmium This observation shows that conditions in the arc are not favourable for emission of band B of zinc although they still may be for B of cadmium This, however, again indicates that the source of the emission maximum at 2212 in the cadmium arc is an impurity.

Deamination in Virus-infected Plants

BONCQUET[1] noticed increased production of ammonia in curly top of beets and in tobacco mosaic and traced it to the presence of denitrifying organisms occurring in association with the diseased plants Jodidi and co-workers observed similar increase in spinach blight[2], spinach mosaic[3] and cabbage mosaic[4] and attributed it to denitrification since there was diminution in total nitrogen The latter authors indicated the possible formation of hydroxy acids, but did not study the related acid metabolism

In the course of an inquiry on the mechanism of increased formation of ammonia in spiked sandal, I noted distinct increase in hydroxy acids, especially malic, in the earlier stages. In the more advanced condition, succinic acid was found to be present in the diseased tissues while it was entirely absent from the healthy ones These observations having suggested the presence of an active deaminase in infected plants, a series of quantitative studies were carried out, adopting the method of Kisch[5]

The following were some of the results obtained

Deaminase activity of healthy and spiked sandal

Time in hours	Ammonia (in c c $N/50$) produced by 1 gm of leaf powder		Carbon dioxide (in c c $N/50$) produced by 1 gm of leaf powder	
	Healthy	Spiked	Healthy	Spiked
1	0 2	0 8	0 8	1 4
4	0 5	2 7	2 1	4 7
8	0 8	5 8	3 4	9 6
14	1 2	9 2	5 1	16 8

It is clear from the above that the increased production of ammonia is due to greater oxidative deamination in the diseased tissues Further work on these and other aspects is in progress and will be published shortly in the *Journal of the Indian Institute of Science*

Interconvertibility of Glucose and Fructose in Plant Tissue

IN a recent paper from this laboratory[1] it was shown that sucrose is formed both from glucose and from fructose when starch-depleted leaves of red clover or wheat plants are placed in 10 per cent solutions of these hexose sugars in the dark This result was explained by assuming that glucose and fructose are transformed into each other in plant tissue

Continued research has now confirmed the above assumption The experiments were made with several plant species, both grasses and legumes The plants were first kept in the dark for forty-eight hours to deprive them of starch, whereupon they were placed in 10 per cent sugar solutions so that the ends of the stems were immersed while the leaves did not come into direct contact with the liquid After a further twenty-four hours in the dark the leaves were cut off from the stems and dried and analysed separately The drying was carried out *in vacuo* at 100°.

The results show that glucose and fructose are indeed easily converted into each other in plant tissue The transformation takes place already in the stems, which is also the seat of sucrose synthesis These reactions are not affected by an addition of 10 per cent toluene to the sugar solutions, and are only slightly retarded by a 0 05 molar potassium cyanide solution There was evidence that in leaves part of the glucose disappears, possibly as a result of respiration Under the conditions of the experiment, the synthesis of starch was very slight or nil. The stalks of horse beans were found to contain much more invertase than the leaves

The following experiment with horse beans will illustrate the quantitative proportions in question. 20 plants were used for each determination All values are computed on a 'residual-dry weight' basis.

	Dry matter Per cent	Total soluble sugars	Glucose	Fructose	Sucrose	In-soluble sugars
N leaves	9 05	7 35	0 7	4 35	0	4 3
N stems	6 0	7 1	0 7	4 6	0	10 25
D leaves	7 75	3 9	0	2 9	0	5 6
D stems	5 55	1 9	0	1 9	0	10 85
G leaves	11 65	17 3	6 2	3 6	5 1	7 0
G stems	8 0	26 25	12 2	7 55	5 15	11 2
F leaves	13 3	17 2	2 95	7 05	6 5	5 3
F stems	8 1	29 15	8 7	14 8	7 25	10 6

(N = normal plants, D = plants kept in the dark for forty eight hours, G = plants kept in 10 per cent glucose solution for a further twenty-four hours, and F = plants kept in 10 per cent fructose solution for twenty-four hours)

[1] Virtanen, A I, and Nordlund, M, *Biochem J*, 28, 1729, 1934

Spectrum of Nova Herculis, 1934

IN many respects the most recent nova is following the usual course in its spectral changes The present spectrum is a medley of bright bands and of absorption lines the bright hydrogen bands are accompanied by a number of absorption components on the side of shorter wave-length, while corresponding to each component and with the same Doppler displacement are a number of absorption lines due to atoms of Fe^{+}, Ti^{+}, Cr^{+}, Ca^{+}, etc

The chief feature of interest in the spectrum now is the emergence of several bright forbidden lines of O I, first weakly visible in the spectrum of December 27, 1934 They are increasing in brightness and now stand out from the rest of the spectrum, conspicuous both by their strength and by the absence of accompanying absorptions They are the exact analogues in the spectrum of O I of three well-known lines in the spectra of nebulæ and novæ, which are forbidden lines of O III The first of the three lines of O I has been identified with the principal auroral line. The other two lines of O I have been observed in nebulæ also[1] but have not previously been found in novæ The two sets of lines are

O I		O III	
5577	$p^4\,{}^1D_2 - p^4\,{}^1S_0$	4363	$s^2p^2\,{}^1D_2 - s^2p^2\,{}^1S_0$
6300	$p^4\,{}^3P_2 - p^4\,{}^1D_2$	5007	$s^2p^2\,{}^3P_2 - s^2p^2\,{}^1D_2$
6364	$p^4\,{}^3P_1 - p^4\,{}^1D_2$	4959	$s^2p^2\,{}^3P_1 - s^2p^2\,{}^1D_2$

Points from Foregoing Letters

A DEFINITE relation is found by Prof J H. Orton between the mean diameter, or the mean axis, of the English native oyster and the volume of the entire animal; this relation is similar to that between the diameter, or thickness, and volume of a segment of a sphere Prof Orton supplies graphs showing these relations in oysters from several localities He indicates upon the graphs the age of the oysters, known in a few cases from tank experiments and estimated empirically in the remaining instances from local knowledge Prof Orton believes that the probable increase of the stock on an oyster-bed in a given time could be predicted, given sufficient observations

Photographic plates impregnated with borax register the action of neutrons (from a radon-beryllium source) upon the boron atoms in the borax Messrs H J Taylor and M Goldhaber have found some 50,000 microscopic tracks produced per square centimetre, and from the length of these tracks they confirm the previous deduction that boron atoms are transmuted to lithium plus helium Similar experiments show that lithium acted upon by neutrons gives helium plus hydrogen atoms of mass 3 These nuclear reactions release several million volts of energy

Neutrons, the most efficient agents in atomic transmutations, can be directed or canalised along tubes having walls made of a substance of high hydrogen content. This prediction by Dr Szilard has been confirmed by Prof. F. L Hopwood and Mr T. A. Chalmers, who used hollow cylinders of paraffin wax A graphite tube also gave a small canalisation effect, but none was observed with impure ebonite

If the spin of the electrons be taken into consideration, the value of the 'absolute field constant' calculated by Born and Infeld ($9\cdot18 \times 10^{15}$ E.S U.) is considerably diminished Drs. Max Born and E. Schrödinger estimate roughly that its value is decreased about twenty-fold, while the radius of the electron is increased ten-fold.

From a comparison of determinations of longitude in 1870 and 1932, Sabine I., East Greenland, seems to have drifted westwards several hundred metres. Dr L Hawkes advocates the establishment, in specially selected parts of the world, of stations specially fitted to determine by astronomical observations the occurrence of lateral drift He points out that the results would throw light on the mechanism of mountain building; it should also prove or disprove Wegener's theory, which assumes that the continents are the broken pieces of a sheet of lighter and more acid rock 'floating' upon a denser and more basic rock, and that they are still moving laterally

A large increase in respiration by organs of various invertebrate animals, under the action of thyroid extract, is reported by Dr Rivka Ashbel Comparative figures are given for the eggs of silkworms, crabs and molluscs, and the ovary of the sea-urchins and sea-squirts

In NATURE of February 23, Prof Robertson supported his earlier observations that cadmium vapour emits ultra-violet light of wave-lengths 2212 A by pointing out that the cadmium arc emits such light, and that the zinc arc emits the corresponding light of wave-lengths 2060 A Prof. J. G Winans and Mr. S W Cram now write that the zinc arc shows no corresponding *maximum* at 2060 A, and maintain that the 2212 band observed by Robertson is probably due to an impurity such as cadmium oxide or hydride

Mr A V V. Iyengar has observed in 'spiked' sandal an increase not only in ammonia but also in hydroxy-acids (malic and succinic) He suggests that these are formed by an active deaminase (an enzyme capable of replacing the $-NH_2$ group of amino-acids by the $-OH$ group of water, leading to the formation of hydroxy-acids and ammonia). The same deaminase may be responsible for the increased production of ammonia in tobacco mosaic, spinach blight and mosaic, etc

It has been found that ordinary cane-sugar (sucrose) is formed by starch-free plant leaves from either glucose or fructose alone, although its molecule is made up of both these simpler sugars. M. Nurmia now reports further experiments showing that plant tissues have the property of changing glucose into fructose.

Research Items

Early Man in China. Further researches and discoveries at Choukoutien, the site of discovery of Peking man, are described in three recent communications to the Geological Society of China. Messrs. Ralph W Chaney and Lyman H Daugherty deal with the occurrence of *Cercis* in association with the remains of *Sinanthropus* (Bull. 12, No. 3). Fragments of charred wood pointing to the use of fire by Peking man have been identified as a new species of *Cercis*, a member of the family of Leguminosæ. In honour of the late Davidson Black it is named specifically *Blackii*, but it is sufficiently akin to *C. chinensis*, common in Chili Province, to suggest the probability that the climate in Peking man's day was much as it is now P Teilhard de Chardin and Dr. W C Pei report on discoveries in 1933–34 at Choukoutien (Bull 13, No 3) which, while not altering previous conclusions, add distinctness to precedent views on the stratigraphy and physiography of late Cenozoic times in north China It is now apparent that the Lower Pleistocene, unknown for so long, is one of the most important Cenozoic formations in north China New localities in the form of pockets have been opened up which make it possible to distinguish five, or even six, stages, instead of the three sedimentary units and the single fossiliferous horizon (*Sinanthropus* beds) previously differentiated. A preliminary report on the late palæolithic cave is presented by Dr W C Pei (Bull. 13, No 4) in which the archæological and palæontological finds are described. Five cultural layers were found Three human skulls and a large series of other human bones were discovered and among the artefacts 28 perforated teeth (canines) of fox or badger, which by their juxtaposition suggest the use of teeth as a necklace. As possibly younger than the remains of southern Ordos and older than Hailar, a tentative dating as equivalent to Magdalenian man in Europe is suggested.

Beehive Graves in the Sudan and Sinai. Mr. G. W Murray describes and figures in *Man* of February six beehive tombs, closely resembling the *nawamis* of Sinai or the *rijjum* of Arabia, which he discovered in 1926 in the neighbourhood of the fishing village of Halaib on the Red Sea coast. Superstructures had been erected over the original interment by corbelling until a beehive of three metres internal diameter at base and 1·7 m. high had been formed with an aperture in the roof large enough to admit the passage of a man. Outside this a dry stone tumulus six metres in diameter had been piled up rather untidily. The Sinai *nawamis* differ from the Halaib graves by having a neatly built retaining wall around them. Two graves were examined and in each at about 20 cm depth very much decomposed bones covered with stones were discovered. The only objects found with them were two copper rings They appeared to be pre-Islamic, but of no very great antiquity. They recall the more elaborate graves described by Schweinfurth from Gebel Maman. Sinaitic *nawamis* excavated by Currelly were found to contain shell ornaments and flint arrow-heads belonging to a primitive race, but not necessarily very early in date. Corbelling in mud brick occurs at a very early date in Egyptian tombs. Dr. Reisner, in a private letter which is quoted, refers to Second Dynasty examples and says that he now assigns the use of rude brick corbelling to the last king of Dynasty I Therefore the practice of corbelling seems to have originated in mud-brick in the Nile Valley about the time of the First Dynasty, to have been copied in rubble masonry by the inhabitants of the desert, and to have spread north-eastward into Sinai and Northern Arabia and south eastward into the Sudan and Eritræa, where it is not yet quite extinguished by the Moslem type of burial

Influence of Light upon Goatsucker's Song Gilbert White shared the general impression that the song of the goatsucker begins "exactly at the close of day", but S E Ashmore's observations in Surrey and Glamorgan carried on during three summers, show that there is a considerable amount of variation (*British Birds*, February, p. 259, 1935) In the course of the day, there are generally two spells of song, one commencing after sunset, the other before sun rise The former began 18–101 minutes after sunset, the latter between 123 minutes and 27 minutes before sunrise, but the average times respectively are about 35 minutes and 50 minutes It would seem that light intensity is one factor in determining the song, for the presence of bright moonlight delayed the commencement of the evening song, though it is not so easy to understand why it should have hastened the commencement of the morning song to the extent of more than half an hour before sunrise Another problem lies in the seasonal variation of the periods, which are longer in mid July than in June or August, although light conditions are not then at their highest The author hazards the suggestion that there may be a "connexion with the hour at which are found flying the moths and other creatures which form the bird's food"

Deep-Sea Fishes and a New Trawl Mr Eide Parr ("Report on Experimental Use of a Triangular Trawl for Bathypelagic Collecting with an Account of the Fishes obtained and a Revision of the Family Cetomimidae" *Bull. Bingham Oceanographic Coll*, 4, 1934 Contribution No 35, Woods Hole Oceanographic Institution) describes a trawl which was successfully used during the first Caribbean cruise of the *Atlantis* sponsored jointly by the Woods Hole Oceanographic Institution and Yale University The large triangular trawl, 50 ft long each side of the opening and with three otter boards, was provided by the Bingham Oceanographic Foundation of Yale University Although difficulties in equipment and arrangements were great, one haul was extremely successful, showing that with certain alterations, easily made on land, this trawl should be a valuable addition in deep-sea collecting to supplement the results obtained by the smaller nets Many large fish are caught, but not so many small specimens, owing to the coarser mesh. The one successful haul yielded a total of 47 species of fish and 491 individuals, 373 of which belonged to the genus *Cyclothone* The author, having examined a large number of samples from the east central Atlantic, concludes that there are only three species of this genus in the area studied—*C. braueri*, *C pallida* and *C microdon*. Several new species are described and a new sub-family and genus. Among the new species is a male *Borophryne*, agreeing in all essentials with *B. apogon* of Regan and Trewavas,

but differing in the number of rostral spines and in other minor points As the author states, "it is thus for the first time possible to introduce a new Ceratoid species referred to its proper genus on the basis of a still unattached male only"

Silicoflagellates and Tintinnids of the Great Barrier Reef. Dr S M. Marshall (Great Barrier Reef Expedition 1928–29 Scientific Reports British Museum (Natural History) 4, No. 15, 1934) shows that silicoflagellates are rare in the material available since their small size enables them to pass through the meshes of the finest net By centrifuging the water samples it is found that they were present in small numbers, but show no seasonal variation. The Tintinnoinea were captured in the tow nettings taken with the international fine silk not described by Russell and Colman (2, No 2, 1931) They fall into two groups, those adapted to neritic conditions, and those of oceanic habitat which are restricted to water of relatively high salinity Neritic species are common throughout the year, but especially in March Oceanic species are rarer and occur mainly in August and September from the weekly stations when the salinity inside the barrier was more than 35 per cent Fifty-six species are recorded, twenty-two being cosmopolitan and known from the Atlantic, Pacific and Indian Oceans, sometimes from temperate and even arctic regions Nine species are restricted to warm seas Results from stations on or near the outer reefs suggest that there is a rich tintinnid fauna in the ocean waters outside, of which only some species can live permanently within the barrier Three species are new to science Several forms hitherto only known from the eastern tropical Pacific are now recorded from the western Pacific also

Vegetative Propagation at Edinburgh. For a long time horticulturists have regarded the Edinburgh Botanic Gardens as the place to which to turn for advice and help in matters of plant propagation This has been largely due to the general willingness of the staff to help, but also to the great interest of the late L B Stewart in the problem of vegetative propagation Dr. R J D Graham, who was closely associated with his work, has now stated briefly some of the main conclusions reached by Stewart during his long struggle with the practical problems associated with vegetative propagation (*Trans Proc Bot Soc Edin*, 31, Part 3, 1934) One difficulty is to know when to make the cuttings A general guide is to take the cutting when the season's growth is completed, when reserve foods for next season's growth are being accumulated and when at the same time vigorous cells capable of wound protection are still present Stewart had cuttings taken of many plants every month, and from these data a list is now published by Dr. R J D Graham showing in what months successful (more than ninety per cent) propagation was obtained.

Potato Diseases in Great Britain. The Ministry of Agriculture and Fisheries has recently issued a new portfolio of "Leaflets on Diseases of Potatoes" as No 3 of its series of collected leaflets (London: H.M. Stationery Office, pp 45, 1*s* 6*d* 1934) This loose-leaflet volume replaces No 3 of the older sectional volumes, "Cultivation and Diseases of Potatoes" Three leaflets on potato-growing and the selection of seed tubers are omitted, as the subject-matter is to be expanded into a new bulletin Six of the original leaflets have recently been revised, and issued as advisory leaflets, in which form they are included in the new portfolio They deal with common scab, the Colorado beetle, powdery scab, black-leg, mosaic and virus diseases, and dry rot Advisory leaflet No 71, on the Colorado beetle, is enriched with a new coloured plate, while there are more half-tone illustrations than formerly A seventeen-page insert has been printed specially for the new collection, and briefly describes nine miscellaneous diseases, namely, skin spot, spraing, black scurf and stem canker, violet root-rot, white root-rot, pink rot, watery wound rot, *Verticillium* wilt, and silver scurf. Potato blight, wart, *Sclerotinia* rot and leaf-roll diseases, are adequately described by the inclusion of four older leaflets

Distribution of Earthquakes. A new map by Capt. N H Heck of the distribution of earthquakes throughout the world is published in the *Geographical Review* of January 1935 It is based mainly on the location of epicentres instrumentally determined during the period 1899–1933 To these have been added epicentres of major earthquakes of historical record especially in China, Syria and the Lesser Antilles The map shows clearly two great belts of activity Of these, the more striking is the Mediterranean-Pacific belt, which appears to girdle the earth via the Mediterranean, southern Asia, the north Pacific and West Indies, with main branches southward via the Malay Archipelago and New Guinea to New Zealand and from the West Indies into South America The second belt is that of the mid Atlantic, and this is entirely oceanic and is marked by few major shocks, but of course there is less scope in this belt for instrumental records It is noticeable that practically all the great ocean deeps are within the belts and all the largest rifts on the land surface are within the great belt or its branches There would appear to be no belt crossing the Pacific Ocean, the branch to Easter Island being linked to South America In the South Atlantic, a detached area around the South Sandwich group may prove to be an extension of the mid Atlantic belt

Overhead Irrigation Investigations into the methods and value of overhead or spray irrigation in Australia have been made at the Commonwealth Research Station at Griffith, New South Wales, and some conclusions are published in Pamphlet No 50 of the Council for Scientific and Industrial Research, Melbourne ("The Design of Overhead Irrigation Systems", E S. West and A Howard) The system depends on the distribution of water under pressure from orifices in lateral pipes branching from the mains These laterals are 1-in pipes placed on the ground They can easily be moved from place to place or rotated to ensure complete irrigation The advantages of the system compared with surface methods are the greater control over the quantity and distribution of the water, the absence of water-logging which may occur near irrigation trenches, the lack of need of ditches and levees with a consequent saving of ground and the added possibility of irrigating at will an area not previously prepared, and lastly a great saving in labour There are, however, some disadvantages in the system, including the initial cost, depreciation, of plant and the cost of pumping the water. The authors believe that the spray system is cheaper and more advantageous than surface irrigation on undulating land with light soils, and that the converse is true on heavy flat land.

Flow of Colloidal Systems. Dr A. S C Lawrence (*Proc. Roy Soc*, A, Jan. 1) has examined the flow of colloidal liquids, which do not in general behave as simple viscous liquids. The flow was investigated by suddenly changing the flow through a glass tube from colourless solution to solution containing a dye, and photographing the advancing boundary of colour. This boundary is parabolic for ordinary viscous liquids The colloidal systems fall into two classes. in one the resistance is small at the wall of the tube, rises rapidly to a maximum and falls off again to the centre of the tube, in the other, the 'gelating' class, the resistance to flow increases as the axis of the tube is approached Some of the colloidal solutions show very marked elastic properties The anomalous flow is interpreted as due to the mutual interference of large, non-isodimensional (that is, elongated) micelles

Absolute Measurement of X-Rays with a Geiger Counter G L. Locher and D P Le Galley (*Phys Rev*, Dec 15, 1934) have applied the Geiger-Muller counting tube to the absolute measurement of X-ray intensities A narrow beam of X-rays is passed through a counter in such a way that only electrons liberated in the gas of the counter are counted Using krypton at 6·3 cm pressure and zirconium fluorescent K-radiation, the absorption of the rays in the gas column is known to be 3 75 per cent, and since the number of electrons corresponding to this absorption is counted, the number of quanta in the beam may be deduced The scattering of the beam may be neglected compared with the fluorescent absorption The beam calibrated in this way was used to obtain the sensitiveness of Eastman X-ray film The minimum visible blackening was obtained with $7 \cdot 2 \times 10^6$ quanta per sq. cm A curve connecting the blackening of the film with the incident quanta is published

Action of Alternating Magnetic Fields upon Ferromagnetic Particles. About twelve years ago, W. M. Mordey described experiments on the action of single and multi-phase alternating magnetic fields on ferromagnetic particles (see *Proc Phys Soc*, **40**, 338; 1928). The phenomena observed suggested that under certain conditions there was a repulsion of the particles from strong to weak field regions. Thus when the particles were strewn on a surface above a series of vertical magnets excited alternately by two-phase current, they moved in the direction opposite to that of the movement of the successive alternate north and south poles to which the arrangement corresponds. No satisfactory interpretation of the phenomena was given Further experiments have been made by H Stafford Hatfield (*Proc Phys Soc*, **46**, 604; 1934), using particles of iron, steel, magnetite and pyrrhotite No anomalous repulsive action was observed when the particles were attached by adhesive to one arm of a torsion balance, or when the particles were allowed to fall freely through the fields. The essential factors involved may be appreciated by considering the effect on a magnetised particle resting on a surface due to a moving vertical magnet, or series of magnets, below the surface. Owing to friction, the horizontal force on either pole of the particle will be effective only when that pole is raised from the surface; that is, after the upward vertical force has passed a definite value The particle as a whole will, therefore, move oppositely to the magnets below, each pole of the particle stepping out alternately. It is clear that remanent magnetism is necessary for these effects to occur, and that their magnitude will depend on the shape and mass of the particles as well as on their magnetic characteristics The behaviour of particles under more complex conditions can readily be given on the above basis
